PUBLISHED BY HIS MAJESTY'S STATIONERY OFFICE

To be purchased directly from H.M. STATIONERY OFFICE at the following addresses

Adastral House, Kingsway, London, W.C.2; 120 George Street, Edinburgh 2

York Street, Manchester 1; 1 St. Andrew's Crescent, Cardiff

80 Chichester Street, Belfast  
or through any Bookseller

1934

Price 6s. *od.* net. In cloth, 8s. *od.* net.

## PREFACE

The *Nautical Almanac* for 1935 follows the revised arrangement introduced in 1931. Advantage has been taken of the occasion of a change of printer to introduce various typographical improvements.

Variations have been replaced throughout by finite differences, which lend themselves more readily to interpolation.

The practice of giving logarithms of tabular quantities instead of their natural values is being abandoned, because of the more general use of calculating machines. Logarithms are no longer used in the Nautical Almanac Office. In this *Almanac* natural values of the true distance of Mercury from the Earth are given, as well as of some of the Besselian elements of eclipses. In the *Nautical Almanac* for 1937 the logarithms of the Besselian day numbers  $A$ ,  $B$ ,  $C$ ,  $D$  will not appear.

The *G.M.T. of Transit of the Sun at Greenwich* is given for the first time (pages 22-29). This serves the purposes formerly served by the equation of time at apparent noon.

The *Besselian Day Number E* is now given at the foot of each page of Besselian day numbers (pages 266-273). The *Cape Independent Day Numbers*  $1 + x$ ,  $1 + y$  and  $g' \div g_0$  are given for the first time (pages 275-289).

In the *Mean Places of Stars* (pages 296-307) some of the footnotes relating to double stars have been omitted, as the purpose of these footnotes is merely to prevent possible confusion or misidentification when observing with a transit instrument. The mean right ascensions of *Circumpolar Stars* (page 307) are now given to two decimals only.

In the *Besselian Elements of Eclipses* (pages 522-535) the former logarithmic values of  $\sin d$ ,  $\cos d$ ,  $\tan f_1$  and  $\tan f_2$  have been replaced by natural values.  $x'$  and  $y'$  are not given, as they may be deduced from the differences of  $x$  and  $y$ . The expressions for  $\xi'$  and  $\eta'$  applicable to each eclipse are included with the Besselian elements for the first time. An example of the calculation of the local circumstances of a partial solar eclipse has been given (page 805); an example of the calculation of the local circumstances of a total solar eclipse will be given in the *Nautical Almanac* for 1936. Various formulæ enabling quantities required in connection with eclipse observations to be computed in terms of the Besselian geometry have been given (page 804).

The occultation machine lent by Mr. J. D. McNeile has again been used to enable the elements of occultations to be deleted in cases where the occultation is not visible from any fixed observatory under favourable observing conditions with respect to altitude and darkness. A new machine is being constructed by a professional instrument maker, and will be used for the occultations for 1937.

Four pages of new tables relating to the *Satellites of Saturn* have been given (pages 838-841). Although appearing this year in the *Explanation*, they will be found in future issues in the pages devoted to *Satellites of Saturn*. They are based

on the recently published elements of the late G. Struve, and are intended to facilitate the prediction of eclipses, transits, shadow transits and occultations during the forthcoming passage of the Earth through the ring-plane. They have, however, been calculated from the elements with a rigour that will enable them to be used in the comparison of future observations with theory. A paper dealing with the prediction of satellite phenomena from these tables is being contributed to the *Memoirs of the British Astronomical Association*.

In the *Phenomena* (pages 640–641) the conjunctions of planets in pairs have been omitted if the difference of declination is greater than  $3^\circ$ .

The auxiliary interpolation tables (*Tables XVI–XXI*) have been revised and extended to cover the methods of interpolation most suitable for the material in the *Nautical Almanac*. They will also be found useful for the interpolation of other tables in which fifth and higher order differences are negligible.

The article on *The Calendar* (pages 754–770), written by Dr. J. K. Fotheringham, Reader in Ancient Astronomy and Chronology in the University of Oxford, has been revised and a new paragraph on *Subdivisions of the Day* added.

The *Explanation* has been revised and amplified. The principal additions are to be found under the headings *Eclipses* (page 800), *Satellites of Saturn* (page 834) and *Tables XVII–XXI* (page 851).

The *Sun's Co-ordinates X, Y, Z*, referred to the equinox of the beginning of the year (pages 30–37) will be omitted in the *Almanacs* for 1938 and later years; the co-ordinates referred to the equinox of 1950.0 (pages 46–53) will be retained. The heliocentric longitude, latitude and radius vector of Mercury will also be omitted for the first time in the *Nautical Almanac* for 1938.

The volume of *Planetary Co-ordinates for the Years 1800–1940 referred to the Equinox of 1950.0* has been published; a description will be found on page 777. Work has been begun on the volume for 1940–1960.

Another Nova-Brunsviga calculating machine, Model IVA, and a Hollerith 80-column punch were added to the equipment in 1933. Preparations are being made for doing a series of about 800,000 multiplications by the Hollerith Multiplying Punch. A 6-register National (formerly called the Ellis) machine was acquired in 1934 January; this machine will integrate a function from its sixth finite differences or difference a function to the fifth difference, printing the function and all its differences. Its introduction has led to new and improved technique in sub-tabulation, of which a full account will be given later.

The following papers, dealing with the equipment or methods of the Nautical Almanac Office, were published in 1933.

- (1) "The Computation of Total Solar Eclipses." *M.N.R.A.S.*, **93**, 175, 414 and 538.
- (2) "The Total Solar Eclipse of 1940 October 1." *M.N.R.A.S.*, **93**, 181.
- (3) "Computing the Nautical Almanac." *Nautical Magazine*, 1933 July.
- (4) "The Hollerith and Powers Tabulating Machines." Privately printed.

By international arrangement certain portions of the *Nautical Almanac* are supplied from the offices of the *American Ephemeris*, the *Connaissance des Temps*, the *Berliner Jahrbuch*, and the *Almanaque Nautico*, in exchange for portions of the *Nautical Almanac* supplied to those offices. These are as follows:—

## PREFACE, 1935

v

*From Washington.*—Apparent places of stars marked A.E. at the foot of the column; eclipses; elements of occultations; satellites V, VI and VII of Jupiter; satellites of Saturn (except differential co-ordinates of Hyperion and Iapetus, and tables on pages 838–841); satellites of Uranus and Neptune; physical ephemerides of Sun, Moon (except position angle of terminator and fraction illuminated), Mercury, Venus, Mars and Jupiter; sunrise, sunset, moonrise and moonset; azimuth of Polaris at all hour angles.

*From Paris.*—Apparent places of circumpolar stars; eclipses; Jupiter's four great satellites.

*From Berlin.*—Apparent places of stars marked B.J. at the foot of the column; rings of Saturn; differential co-ordinates of Hyperion and Iapetus.

*From San Fernando.*—Apparent places of stars marked A.N. at the foot of the column.

The footnotes on pages 296–307 relating to double stars were kindly supplied by Dr. R. G. Aitken, Director of the Lick Observatory, Dr. W. H. van den Bos, of the Union Observatory, Johannesburg, and Professor G. van Biesbroeck, of the Yerkes Observatory.

The late appearance of this *Almanac*, which is due to causes beyond the control of the Superintendent, is much regretted. It is anticipated, however, that it will be possible to advance the date of publication of future *Almanacs*.

Thanks are due to the printers, Messrs. C. Tinling and Co., Ltd., for their co-operation in the efforts that have been made to establish standards for the presentation of tabular matter and of mathematical-astronomical text.

The staff at present consists of:—

*Superintendent.*—L. J. Comrie, M.A., Ph.D., F.R.A.S.

*Deputy Superintendent.*—D. H. Sadler, M.A., F.R.A.S.

*Temporary Senior Assistant.*—H. W. P. Richards, B.Sc., F.R.A.S.

*Junior Assistants, Higher Grade.*—A. J. Daniels  
S. G. Daniels

*Junior Assistants.*—W. A. Scott, B.Sc., F.R.A.S.  
N. H. Harrild (acting)  
E. Smith (acting)

*Computing Assistants (Women).*—Miss W. D. White  
Miss M. E. Williams (acting)

*Temporary Computers.*—Miss L. H. Burr  
Miss M. R. Rodgers

*Secretary.*—Miss M. M. Roberts

In addition a number of piece-workers are employed.

L. J. COMRIE  
*Superintendent*

*H.M. Nautical Almanac Office*  
*Royal Naval College*  
*Greenwich*  
*London, S.E.10.*

1934 April.

## ERRATA, 1935

### *Nautical Almanac for the Year 1928*

Page 174. Apparent Declination, September 13. For  $3^{\circ} 30' 09''.4$  read  $3^{\circ} 20' 09''.4$

### *Nautical Almanac for the Year 1933*

Page 166. Upper Transit, Apparent Geocentric Declination of Centre, March 7. For  $+24^{\circ} 39' 35''.6$  read  $+24^{\circ} 39' 25''.6$

Page 502. Footnote. For July 9 read August 9

### *Nautical Almanac for the Year 1934*

Pages 640–641. The greatest elongation of Mercury falls on July 31 according to the criterion on page 812. If the latitude of the planet is taken into account, the greatest elongation is on August 1.

### *Nautical Almanac for the Year 1935*

Page 155. Moon's Right Ascension, December 1<sup>d</sup> 8<sup>h</sup>. For 29<sup>h</sup> read 20<sup>h</sup>

31-0	Th.	30	·082	833·5					S.	89	·244	892·5

The Day of the Year and the Fraction of the Year are reckoned from January 1<sup>st</sup> 0<sup>h</sup>, and the latter is based on the tropical year of 365·2422 days. To obtain the Fraction of the Year from the commencement of the Besselian fictitious year (1935-0 or 1935 Jan. 1<sup>st</sup>-290), or the time when the Sun's mean longitude, affected by aberration, is 280°, the above fractions must be diminished by ·001.

The Julian Day commences at noon.

The Day of the Year and the Fraction of the Year are reckoned from January 1<sup>st</sup> 0<sup>h</sup>, and the latter is based on the tropical year of 365·2422 days. To obtain the Fraction of the Year from the commencement of the Besselian fictitious year (1935·0 or 1935 Jan. 1<sup>st</sup> 290), or the time when the Sun's mean longitude, affected by aberration, is 280°, the above fractions must be diminished by ·001.

The Julian Day commences at noon.

## Mean Elements of Sun

Epoch	...	1935 Jan. 1 <sup>d</sup> 0 <sup>h</sup>
Mean longitude	= $L$	279° 43' 09".9
Mean anomaly	= $g$	357 53 48.6
Mean longitude of perigee	= $\pi$	281 49 21.3
Log semi-major axis	= $\log a$	0.0000001
Eccentricity	= $e$	0.0167364

## PRECESSIONAL CONSTANTS

Mean obliquity =  $\epsilon$   $23^{\circ} 26' 51''.86$   
 $= 23^{\circ}.44774$

	Natural No.	Logarithm
$\sin \epsilon$ ...	0.3979 1244	9.599 7875
$\cos \epsilon$ ...	0.9174 2340	9.962 5698
$\tan \epsilon$ ...	0.4337 2825	9.637 2177
$\cot \epsilon$ ...	2.3055 911	0.362 7823
$\sec \epsilon$ ...	1.0900 093	0.037 4302
$\operatorname{cosec} \epsilon$ ...	2.5131 157	0.400 2125
General precession = $p$	50".2642	$= 0^{\circ}.0139623$

Precession in R.A. = $m$	3".07299
Precession in Dec. = $n$	18.33626
	$= 20''.0439$

$\log n^s$  0.125890  $\log n''$  1.301981

Ascending node of moving ecliptic on fixed ecliptic =  $\Pi$   $174^{\circ} 16'.22$   
 $= 174^{\circ}.270$

Speed of rotation of ecliptic =  $\pi$   $0''.4708$   
 $= 0^{\circ}.0001308$   
 $\log \pi^s$  9.6729  $\log \pi^{\circ}$  6.1166

For reduction from  
 1935.0 to 1950.0 1950.0 to 1935.0

This table should be used without interpolation, using the date nearest to the date of observation, and the value of  $\alpha$  nearest to the right ascension of the star.

The maximum value of the differential aberration for two objects separated by  $1^\circ$  is of the order  $0^s.02 \sec \delta$  in right ascension, or  $0''.3$  in declination.

If  $\Delta\alpha$  and  $\Delta\delta$ , in units of  $1^m$  and  $1'$  respectively, are the observed differences of co-ordinates, in the sense moving object *minus* star, the necessary corrections for differential precession and nutation are—

$$\text{In R.A. } j \sin(J + \alpha) \frac{\tan \delta}{15} \Delta\alpha - j \cos(J + \alpha) \frac{\sec^2 \delta}{225} \Delta\delta \text{ in seconds of time.}$$

$$\text{In Dec. } j \cos(J + \alpha) \Delta\alpha \text{ in seconds of arc.}$$

No. 769. The reductions from mean to brighter star vary during the year from  $+0^{\circ}.133$ ,  $-2^{\circ}.32$  to  $+0^{\circ}.134$ ,  $-2^{\circ}.31$ . The signs should be changed for reductions from mean to fainter star.

## NOTATION

*h* = the ratio of the area of the illuminated portion of the apparent disc to the area of the entire apparent disc regarded as circular.

*i* = the angle between the Sun and Earth, as seen from the planet.

$\theta$  = the angle which the line joining the cusps, or extremities of the illuminated portion, makes with the meridian.

*L* = the brilliancy of the disc. The unit of *L* is the amount of light received by an eye from a circular disc with the same albedo as the planet, subtending an angular radius of one second of arc, situated at distance unity from the Sun, and illuminated by the latter as the mean disc of the planet is illuminated.

## SATELLITES OF JUPITER, 1935

APPARENT ORBITS OF THE SATELLITES OF JUPITER AT DATE OF OPPOSITION, MAY 10, AS SEEN IN AN INVERTING TELESCOPE

The orbits are elongated in the ratio of three to one in the direction of their minor axes.

## MEAN SYNODIC PERIODS OF THE SATELLITES

I	d	h	m	s	=	d	h	m	s
I	1	18	28	35.946	=	1.7698	60	49	
II	3	13	17	53.736	=	3.5540	94	17	
III	7	03	59	35.856	=	7.1663	87	22	
IV	16	18	05	06.916	=	16.7535	52	27	
V	11	57	27.635	=	0.4982	36	52		
VI					=	266.00			
VII					=	276.67

APPARENT ORBITS OF THE SEVEN INNER SATELLITES OF SATURN  
AT DATE OF OPPOSITION, AUGUST 31, AS SEEN IN AN INVERTING  
TELESCOPE

The orbits are elongated in the ratio of two to one in the  
direction of their minor axes.

NAMES OF THE SATELLITES	
I	Mimas
II	Enceladus
III	Tethys
IV	Dione
V	Rhea
VI	Titan
VII	Hyperion
VIII	Iapetus
IX	Phoebe

# SUNSET, 1935

643

## LOCAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB), AND ENDING OF EVENING TWILIGHT, MERIDIAN OF GREENWICH, 1935

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian. For southern latitudes see page 662.

Aug. 9	4 50	4 36	4 19	3 55	3 39	3 20	2 52	2 15	1 53	1 20			

Twilight lasts all night at latitude +60°, Apr. 23-Aug. 22; +58°, Apr. 29-Aug. 16; +56°, May 6-Aug. 9; +54°, May 13-Aug. 2; +52°, May 22-July 24; +50°, June 2-July 12.

# SUNSET, 1935

653

LOCAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB), AND ENDING OF EVENING TWILIGHT, MERIDIAN OF GREENWICH, 1935

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian. For southern latitudes see page 662.

# SUNSET, 1935

657

LOCAL MEAN TIME OF SUNSET (SUN'S UPPER LIMB), AND ENDING OF EVENING TWILIGHT, MERIDIAN OF GREENWICH, 1935

To obtain the standard time at any station, increase the local time by the number of minutes the station is west of the standard meridian, or decrease the local time by the number of minutes the station is east of the standard meridian. For southern latitudes see page 662.

## SUNRISE AND SUNSET, 1935

## SUNRISE, SUNSET, AND TWILIGHT FOR SOUTHERN LATITUDES, 1935

In the case of a southern latitude, the time of sunrise, sunset, or beginning or ending of twilight is taken from the main table, with the corresponding northern latitude, not for the given date but for a date about six months earlier or later, which is to be found in the following table. The time taken from the main table must be corrected by the quantity given in the auxiliary table below on the same line as the given date.

*Example.*—1935, May 5, in latitude—38°, required the times of sunrise, sunset, and beginning and ending of twilight.

The auxiliary table gives November 7 as the corresponding date, northern latitude, while the correction is +13<sup>m</sup>.

					<i>Beginning of Twilight</i>	<i>Sunrise</i>	<i>Sunset</i>	<i>Ending of Twilight</i>
					<sup>h</sup> <sup>m</sup>	<sup>h</sup> <sup>m</sup>	<sup>h</sup> <sup>m</sup>	<sup>h</sup> <sup>m</sup>
Main table, Lat. + 38°, Nov. 7	...	...	...	...	05 01	06 31	16 56	18 25
Auxiliary table	...	...	...	...	+13	+13	+13	+13
Local mean time, May 5	...	...	...	...	05 14	06 44	17 09	18 38

The periods during which twilight lasts all night in southern latitudes may be found by substituting for the northern latitudes given in the footnotes, pages 648-655, the corresponding southern latitudes, and for the dates given in those footnotes, the corresponding dates taken from the auxiliary table.

## MOONRISE AND MOONSET, 1935

FOR NORTHERN STATIONS NOT ON THE MERIDIAN OF GREENWICH,  
AND FOR SOUTHERN STATIONS

*For northern stations not on the meridian of Greenwich.*—For longitudes twelve hours or less west from Greenwich obtain the data for the given latitude from the Table for the given date and for the date following; for longitudes twelve hours or less east from Greenwich obtain the data for the given latitude from the Table for the given date and for the date preceding. Subtract the time on the earlier date from the time on the later and multiply the difference by the twenty-fourth part of the longitude in hours and decimals of an hour, positive if west, and negative if east. Apply the product as a correction to the time on the given date.

*For southern stations.*—The instant of moonrise or moonset for any station south of the equator is within a few minutes that of moonset or moonrise, respectively, at a place of the same latitude north of the equator whose longitude is twelve hours different from that of the southern station.

If the southern station is twelve hours or less west from Greenwich, and the phenomenon at the southern station occurs between midnight and noon, the local civil day will be the same at the southern and northern stations. If, however, the phenomenon at the southern station occurs between noon and midnight, the local civil day at the northern station will be one day later than at the southern.

If the southern station is twelve hours or less east from Greenwich, and the phenomenon at the southern station occurs between midnight and noon, the local civil day at the northern station will be one day less than at the southern station. If, however, the phenomenon at the southern station occurs between noon and midnight, the local civil day will be the same at the two stations.

Having thus determined the true civil day at the northern station, compute by the rule for northern latitudes. For the desired local mean time of moonrise at the southern station change the time of moonset at the northern station twelve hours, and *add* the correction computed by aid of the table below. For the desired local mean time of moonset at the southern station change the time of moonrise at the northern station twelve hours, and *subtract* the correction computed by aid of the table below. This correction, expressed in minutes of time, is equal to Moon's parallax in minutes of arc—50 multiplied by the factor taken from the table below. This factor is always positive and is the same for northern and southern declinations.

## FACTOR FOR COMPUTING CORRECTION FOR SOUTHERN STATIONS

# MOONRISE AND MOONSET, 1935

681

FOR NORTHERN STATIONS NOT ON THE MERIDIAN OF GREENWICH,  
AND FOR SOUTHERN STATIONS

*Summary of rule for Southern Stations.*—Compute the opposite phenomenon for a fictitious northern station of the same latitude, but differing by  $12^h$  in longitude, after correcting the date (if necessary) from the third column of the following table:—

Longitude of Southern Station			Time of Opposite Phenomenon at Northern Station	Correction to Date for Northern Station	Final Correction Necessary
West	...	...	$\begin{matrix} h & h \\ 00-12 \\ 12-24 \end{matrix}$	$\begin{matrix} d \\ +1 \\ 0 \end{matrix}$	$-12^h$
East	...	...	$\begin{matrix} 00-12 \\ 12-24 \end{matrix}$	$\begin{matrix} 0 \\ -1 \end{matrix}$	$+12$

To the time thus found apply  $12^h$  with the sign shown in the last column of the table above. Compute the auxiliary correction Factor  $\times$  (Moon's parallax  $-50$ ) and

*Add* for Moonrise at southern station

*Subtract* for Moonset at southern station

If the date thus given is not the one required (as may sometimes happen when the phenomenon occurs near  $0^h$  or  $12^h$ ) a new calculation with a revised date will be necessary. It is to be remembered that on one day a month (near first quarter) there will be no moonset, and on one day (near last quarter) no moonrise.

*Example.*—1935, January 15, local civil date.—Find the time of moonrise and moonset in longitude  $9^h 40^m$  east from Greenwich and in latitude  $37^\circ 50'$  south.

The longitude of the fictitious northern station is  $2^h.3$  west from Greenwich and its latitude is  $37^\circ.8$  N. In accordance with the precepts given above, the civil day at the northern station is January 14 for moonrise and January 15 for moonset.

## OBSERVATORIES, 1935

699

## LIST B—FORMER OBSERVATORIES

Place	Longitude	Latitude	Altitude	Period of Activity	Description
Halifax, England ...	+ 0 07 28 <sup>m</sup>	+53 42 09	— <sup>m</sup>	1872-1905	Obs. of the late Edward Crossley
Hamburg, Germany ...	— 0 39 53.6	+53 33 06	25	1821-1909	Former site of Hamburg Obs.†
Harrow, England ...	+ 0 01 19.9	+51 34 47	66	1882-1922	Obs. of the late Col. Tupman
Hartwell, England ...	+ 0 03 24.3	+51 48 36	—	1831-1866	Obs. of the late Dr. J. Lee
Hastings on Hudson, N.Y.	+ 4 55 29.7	+40 59 25	69	1860-1882	Obs. of the late Henry Draper
Heidelberg,* Germany ...	— 0 34 46.8	+49 24 34	126	1879-1898	Obs. of the late Dr. Max Wolf
Herény, Hungary ...	— 1 06 24.6	+47 15 47	229	1881-1909	Obs. of the late E. Gothard
Ipswich, England ...	— 0 04 55.8	+52 00 33	—	1874-1889	Obs. of the late Col. Tomline, at Orwell Park
Ithaca,* New York ...	+ 5 05 56.5	+42 26 51	—	1889-1902	Former Obs. of Cornell Univ.
Ithaca,* New York ...	+ 5 05 56.0	+42 26 47	256	1902-1915	Former site of Fwertes Obs. of Cornell University
Jena,* Germany ...	— 0 46 20.7	+50 56 16	174	1892-1910	Obs. of the late Dr. Winkler†
Jena,* Germany ...	— 0 46 20.3	+50 55 36	155	1812-1888	Former site of University Obs.
Karlsruhe, Germany ...	— 0 33 35.4	+49 00 30	110	1880-1896	Former site of Baden Obs.§
Kempshot, Jamaica ...	+ 5 11 29.5	+18 24 51	540	1872-1920	Obs. of the late Maxwell Hall
Kensington (London), Eng.	+ 0 00 46.8	+51 30 12	—	1826-1831	Obs. of the late Sir J. South
Kensington (London), Eng.	+ 0 00 49.4	+51 30 03	17	1886-1924	Obs. of the late W. H. Maw
Kew (Surrey), England ...	+ 0 01 15	+51 28 06	6	1769-1840	Kew Observatory¶
Kyoto,* Japan ...	— 9 03 06.7	+35 01 37	55	1910-1929	Former site of Obs. of Kyoto Imperial University
Leiden,* Holland ...	— 0 17 56.6	+52 09 28	—	1632-1860	Former site of University Obs.
Leipzig,* Germany ...	— 0 49 29.9	+51 20 20	155	1791-1861	Former site of University Obs.
Leyton, England ...	+ 0 00 00.9	+51 34 34	—	1854-1886	Obs. of the late J. G. Barclay
Liverpool,* England ...	+ 0 12 00.1	+53 24 48	—	1843-1867	Former site of Liverpool Obs.
Liverpool, England ...	+ 0 11 38.7	+53 25 28	—	1840-1875	Obs. of the late W. Lassell
Lund, Sweden ...	— 0 52 47.5	+55 42 12	60	1658-1867	Former site of Royal Univ. Obs.
Lussinpiccolo,** Italy ...	— 0 57 52.3	+44 32 11	42	1893-1910	Manora Observatory
Mandeville,* Jamaica ...	+ 5 10 02	+18 01 00	640	1912-1926	Branch of Harvard College Obs.
Mannheim, Germany ...	— 0 33 50.4	+49 29 11	98	1775-1880	Former site of Heidelberg* Observatory††
Markree, Ireland ...	+ 0 33 48.4	+54 10 32	45	1824-1902	Obs. of the late E. J. and Col. Cooper
Marseille,* France ...	— 0 21 28.1	+43 17 52	29	1702-1864	Former site of National Obs., at Accoules
Mervel Hill (Surrey), England	+ 0 02 30.2	+51 08 12	128	1903-1910	Obs. of the late J. Franklin Adams
Mundenheim, Germany ...	— 0 33 44	+49 27 30	100	1907-1913	Observatory of Dr. M. Müндler
New Haven,* Connecticut	+ 4 51 42.2	+41 18 36	—	1830-1882	Former site of Yale Univ. Obs.
New York, New York ...	+ 4 55 56.7	+40 43 48	—	1850-1892	Obs. of the late L. M. Rutherford
New York, New York ...	+ 4 55 53.6	+40 45 23	—	1883-1897	Former site of Columbia Univ. Observatory
Oncativo, Argentina ...	+ 4 14 44.8	—31 55 10	280	1906-1908	International Latitude Obs.
Outwood (Surrey), England	+ 0 00 23.7	+51 11 38	119	1896-1924	Obs. of the late W. H. Maw
Paramatta (Sydney) N.S.W.	—10 04 00.2	—33 48 50	—	1827-1855	Obs. of the late Sir T. Brisbane
Pennant Hills, N.S.W. ...	—10 04 15.7	—33 44 31	188	—1932	Branch of Sydney Observatory
Plonsk, Poland ...	— 1 21 31.9	+52 37 40	—	1873-1898	Former site of Jędrzejewicz Observatory†††
Redhill (Surrey), England	+ 0 00 41.2	+51 14 25	—	1853-1870	Obs. of the late R. C. Carrington

\* See also List A.

† Transferred to Bergedorf\* in 1909.

‡ See also Gohlis.

§ Transferred from Mannheim in 1880; transferred to Heidelberg\* in 1896. || See also Outwood.

¶ Now a Physical Observatory. \*\* Formerly in Austria. †† Transferred to Karlsruhe in 1880.

††† Transferred to Warsaw in 1898.

### DATE OR CALENDAR LINE

The Date or Calendar Line is a modification of the line of the 180th meridian, which is drawn so as to include islands of any one group, etc., on the same side of the line.

It may be traced by joining up the following positions :—

Lat. 60° 00' S.	Long. 180° 00'	Lat. 48° 00' N.	Long. 180° 00'
„ 51 30 S.	„ 180 00	„ 52 30 N.	„ 170 00 E.
„ 45 30 S.	„ 172 30 W.	„ 65 00 N.	„ 169 00 W.
„ 15 30 S.	„ 172 30 W.	„ 70 00 N.	„ 180 00
„ 5 00 S.	„ 180 00		

When crossing this line on a westerly course, the date must be advanced one day ; when crossing it on an easterly course, the date must be put back one day.

To obtain the Julian Day Number for any date before the beginning of the Christian Era, the date must first be expressed astronomically, i.e. diminished by 1. Then add the smallest multiple of 1000 years that will convert the date into an A.D. date, take out the Julian Day Number for the A.D. date thus obtained, and subtract 365250 days for each multiple of 1000 years added.

Example :—Required the Julian Day Number of May 5, 1234 B.C.

Astronomical date = - 1233 May 5

2 x 1000 = + 2000

Sum = + 767 May 5

Julian Day Number on January 0 of A.D. 764 ... 200 0108

Days from January 0 to May 0, 3 years later ... 1216

Days from May 0 to May 5 ... 5

Sum = Julian Day Number A.D. 767, May 5 ... 200 1329

Two multiples of 365250 days ... 73 0500

Difference = Julian Day Number May 5, 1234 B.C. 127 0829

NUMBER OF DAYS TO BE ADDED TO REDUCE TO THE BEGINNING OF EACH MONTH

Year	Jan. 0	Feb. 0	Mar. 0	Apr. 0	May 0	June 0	July 0	Aug. 0	Sept. 0	Oct. 0	Nov. 0	Dec. 0
0	0*	31*	60	91	121	152	182	213	244	274	305	335
1	366	397	425	456	486	517	547	578	609	639	670	700
2	731	762	790	821	851	882	912	943	974	1004	1035	1065
3	1096	1127	1155	1186	1216	1247	1277	1308	1339	1369	1400	1430

Note.—From 1582 Oct. 15 to 1583 Dec. 31 inclusive, the numbers given by the above tables must be diminished by 10.

\* The numbers given for the years 1700, 1800 and 1900, which were not Leap Years, are for January - 1, consequently the numbers 0 and 31 for Jan. 0 and Feb. 0 of these years must be increased to 1 and 32. For all other months the two tables are used in the normal manner.

A more extended table for the years 1860-1950 is given in Table II. For the current year see pages 2-5.

## TABLE II

## JULIAN DAY NUMBER

DAYS ELAPSED AT MEAN NOON OF EACH DATE OF THE TABLE

#### FRACTIONS OF A SECOND

The sidereal equivalent of a fraction of a mean time second is equal to that fraction *increased* by the amount in the following critical table.

Fraction of a Second      Amount to be Added

0.000

0.000

0.182

.001

0.547

.002

0.913

.003

1.000

In critical cases ascend.

Sidereal time required = Sidereal time at 0<sup>h</sup> + the sidereal equivalent of the *given* mean time.

*Example*—What is the Greenwich true\* sidereal time at 1935 January 11<sup>d</sup> 19<sup>h</sup> 41<sup>m</sup> 22<sup>s</sup>.93 G.M.T.?

True sidereal time at 11<sup>d</sup> 00<sup>h</sup>      7 18 17.788

Sidereal equivalent of 19<sup>h</sup>      19 03 07.273

“ “ 41<sup>m</sup>      41 06.735

“ “ 22<sup>s</sup>      22.060

“ “ 0<sup>s</sup>.93      0.933

Sum = required true sidereal time 3 02 54.79

\*See page 774. The true sidereal time thus determined includes the effect, at 0<sup>h</sup>, of short-period terms of nutation. This effect may be removed, if desired, by subtracting *f'*, the value of *f'* being that at 0<sup>h</sup>, not at 19<sup>h</sup> 41<sup>m</sup>.

In critical cases ascend.

Mean time *required* = Mean time of the preceding transit  
of the First Point of Aries + the mean time equivalent  
of the *given* sidereal time.

*Example*—What is the G.M.T. on 1935 January 11 when  
the Greenwich true sidereal time is 3<sup>h</sup> 02<sup>m</sup> 54<sup>s</sup>.79?

Transit of the First Point of Aries	<sup>h</sup> <sup>m</sup> <sup>s</sup>
Mean time equivalent of 3 <sup>h</sup>	16 38 58.11
" " 2 <sup>m</sup>	2 59 30.511
" " 54 <sup>s</sup>	1 59.672
" " 0 <sup>s</sup> .79	53.853
	0.788
Sum = required mean time	19 41 22.93

If the given true sidereal time includes the effect of short-period  
terms of nutation, their effect should, strictly speaking, be  
removed by subtracting  $f'$ , the value of  $f'$  being that at the  
moment concerned. In general this refinement is unnecessary.

Let  $\phi$  = Geographical latitude $\phi'$  = Geocentric latitude $\rho$  = Geocentric radius $h$  = Altitude above sea level in metres $H$  = Altitude above sea level in feet

Then—

$$\rho \sin \phi' = (S + 10^{-8} \cdot 0.1568h) \sin \phi$$

$$= (S + 10^{-8} \cdot 0.0478H) \sin \phi$$

$$\rho \cos \phi' = (C + 10^{-8} \cdot 0.1568h) \cos \phi$$

$$= (C + 10^{-8} \cdot 0.0478H) \cos \phi$$

$$\tan \phi' = (0.993277 + 10^{-8} \cdot 0.0011h) \tan \phi$$

$$= (0.993277 + 10^{-8} \cdot 0.0003H) \tan \phi$$

$$\frac{d \rho \sin \phi'}{d \phi} = S C^2 \cos \phi = S C \rho \cos \phi'$$

$$\frac{d \rho \cos \phi'}{d \phi} = -S C^2 \sin \phi = -C^2 \rho \sin \phi'$$

$$\frac{d \tan \phi'}{d \phi} = 0.9933 \sec^2 \phi$$

The above table is for northern declinations. For southern declinations use as argument  $\alpha \pm 12^h$ .

The table is based on the formulæ

$$p_a = 3^s.0730 + 1^s.3362 \sin \alpha \tan \delta$$

$$p_\delta = 20''.043 \cos \alpha$$

For more extended tables of precession in right ascension and declination the *Präzessions-Tafeln* of Richard Schorr, Director of the Hamburg Observatory in Bergedorf, may be consulted.

The above table is for northern declinations. For southern declinations use as argument  $\alpha \pm 12^h$ .

The table is based on the formulæ

$$p_\alpha = 3^s.0730 + 1^s.3362 \sin \alpha \tan \delta$$

$$p_\delta = 20^s.043 \cos \alpha$$

For more extended tables of precession in right ascension and declination the *Präcessions-Tafeln* of Richard Schorr, Director of the Hamburg Observatory in Bergedorf, may be consulted.

$$\alpha_{1950} = \alpha_{1935} + A + A_1 \tan \delta_{1935} + A_2 \tan^2 \delta_{1935}$$

$$\delta_{1950} = \delta_{1935} + D + D_1 \tan \delta_{1935}$$

$A_1$  and  $D$  are taken from Table XIII with argument  $\alpha_{1935}$ . For values of the argument between  $0^h$  and  $12^h$  the sign on the left is to be taken, and for values between  $12^h$  and  $24^h$  the sign on the right.

Using accents to denote quantities taken from these tables with argument  $24^h - \alpha_{1950}$

$$\alpha_{1935} = \alpha_{1950} - A' + A'_1 \tan \delta_{1950} - A'_2 \tan^2 \delta_{1950}$$

$$\delta_{1935} = \delta_{1950} - D' + D'_1 \tan \delta_{1950}$$

# TABLE XVI, 1935

741

## AZIMUTH OF POLARIS

For hour angles  $0^h$  to  $12^h$  *Polaris* is west of north, and for hour angles  $12^h$  to  $24^h$  it is east of north.

*In critical cases ascend.*

Notation :

$$\begin{array}{llll}
 f_{-1} & \Delta_1' & \Delta_1'' & \Delta_1''' \\
 & \Delta_1' & \Delta_1'' & \Delta_1''' \\
 f_0 & \Delta_0' & \Delta_0'' & \Delta_0''' \\
 & \Delta_0' & \Delta_0'' & \Delta_0''' \\
 f_1 & \Delta_1' & \Delta_1'' & \Delta_1''' \\
 & \Delta_1' & \Delta_1'' & \Delta_1''' \\
 f_2 & \Delta_2' & \Delta_2'' & \Delta_2'''
 \end{array}$$

Note that

$$\begin{array}{l}
 \Delta_0'' + \Delta_1' = \Delta_1' - \Delta_1'' \\
 \Delta_0''' + \Delta_1'' = \Delta_1'' - \Delta_1'''
 \end{array}$$

Formulae :

$$\begin{array}{l}
 f_n = f_0 + n\Delta_1' + B''(\Delta_0'' + \Delta_1') + B''\Delta_1'' + B'''(\Delta_0''' + \Delta_1'') \\
 \text{or } f_n = f_0 + n\Delta_1' + E_0''\Delta_0'' + E_1''\Delta_1'' + B'''(\Delta_0''' + \Delta_1'') \\
 \text{or } f_n = L_{-1}f_{-1} + L_0f_0 + L_1f_1 + L_2f_2 + B'''(\Delta_0''' + \Delta_1'')
 \end{array}$$

If the fourth difference is negligible, i.e. less than 20, the last term can be omitted in each case.

For  $n = \frac{1}{2}$ , with fourth differences negligible,

$$f_{\frac{1}{2}} = \frac{1}{18}(-f_{-1} + 9f_0 + 9f_1 - f_2)$$

or, if fourth differences are not negligible,

$$f_{\frac{1}{2}} = \frac{1}{18}(3f_{-1} - 25f_0 + 150f_1 - 25f_2 + 3f_3)$$

For further explanation see page 851.

The effect of fourth differences may be taken into consideration by using  $M'' = \Delta'' - 0.184 \Delta'''$  in Bessel's or Everett's formula instead of  $\Delta''$ . The above table gives  $0.184 \Delta'''$ . The method should not be used if the fourth difference exceeds 1000. For further explanation see page 852.

$$\begin{aligned}
 f_n &= f_0 + n\Delta' + B''(M_0'' + M_1'') + B''' \Delta''' \\
 \text{or } f_n &= f_0 + n\Delta' + E_0'' M_0'' + E_1'' M_1'' \\
 &= (1 - n) f_0 + n f_1 + E_0'' M_0'' + E_1'' M_1''
 \end{aligned}$$

## NOTATION

Throughout the NAUTICAL ALMANAC Roman letters are used for contractions, e.g. R.A. for right ascension, and italic letters for symbols, e.g. *P* for position angle.

In the following lists a few symbols not actually occurring in the NAUTICAL ALMANAC, but well established in spherical and dynamical astronomy, are included; those used for a temporary or special purpose are not included here, but are defined as they occur.

## ITALIC ALPHABET

<i>A, B, C, D, E</i>	Besselian day numbers
<i>A, B, C, a, b, c</i>	Gaussian constants of an orbit
<i>a, b, c</i>	Quantities for reduction for precession
<i>a, b, c, d</i>	Besselian star constants
<i>A</i>	Azimuth
<i>a</i>	Semi-major axis of an orbit; equatorial radius of the earth
<i>b</i>	Heliocentric latitude; semi-minor axis of an orbit; polar radius of the earth
<i>d</i>	Symbol of differentiation
<i>E</i>	Eccentric anomaly
<i>e</i>	Eccentricity; base of natural logarithms = 2.7182818285...
<i>f, g, G, h, H, i</i>	Independent day numbers
<i>f, F</i>	Symbol of a function
<i>G</i>	Galactic longitude
<i>g</i>	Intensity of gravity; sometimes used for mean anomaly (see also <i>M</i> ); galactic latitude
<i>H</i>	Altitude above the horizon
<i>h</i>	Hour angle
<i>i</i>	Inclination to plane of ecliptic
<i>k</i>	Gaussian gravitation constant; constant of aberration; ratio of the Moon's diameter to Earth's equatorial diameter; coefficient of refraction
<i>L</i>	Mean longitude = $\Omega + \omega + M$ ; see also $\odot$ and $\oslash$
<i>l</i>	Heliocentric longitude
<i>M</i>	Mean anomaly (see also <i>g</i> ); modulus of common logarithms
<i>m</i>	Annual precession in R.A.; mass
<i>n</i>	Annual precession in declination; sometimes used for mean daily motion (see also $\mu$ )
<i>P</i>	Position angle, measured from the north towards the east; period of a planet or comet
<i>p</i>	General precession in longitude
<i>q</i>	Perihelion distance; parallactic angle
<i>R</i>	Radius vector of the Sun (or Earth)
<i>r</i>	Radius vector, expressed in astronomical units
<i>T</i>	Time expressed in units of a century; time of perihelion passage
<i>t</i>	Time expressed in years or smaller units
<i>u</i>	Argument of latitude = $\omega + v$
<i>v</i>	True anomaly or angle from perihelion
<i>X, Y, Z</i>	Geocentric equatorial rectangular co-ordinates of the Sun
<i>x, y, z</i>	Heliocentric equatorial rectangular co-ordinates
<i>z</i>	Zenith distance

## GREEK ALPHABET

$\alpha$	Right ascension
$\beta$	Geocentric latitude
$\Gamma$	Mean longitude of perigee
$\Delta$	Difference; symbol of increment; geocentric distance
$\delta$	Declination
$\epsilon$	Obliquity of the ecliptic
$\theta$	Sometimes (but not in <i>N.A.</i> ) used for longitude of ascending node (see also $\Omega$ )
$\lambda$	Geocentric longitude; planetary precession on the equator
$\mu$	Mean daily motion; proper motion
$\xi, \eta, \zeta$	Geocentric rectangular equatorial co-ordinates
$\pi$	Ratio of circumference to diameter; parallax; used by Newcomb for mean longitude of perigee
$\bar{\omega}$	Longitude of perihelion = $\Omega + \omega$
$\rho$	Distance from centre of earth in units of earth's equatorial radius
$\Sigma$	Symbol of summation
$\tau$	Fraction of the year since the commencement of the Besselian fictitious year
$\phi$	Geographical latitude; eccentric angle of an orbit ( $\sin \phi = e$ )
$\phi'$	Geocentric latitude
$\psi$	Luni-solar precession in longitude
$\omega$	Arc from node to perihelion = $\bar{\omega} - \Omega$

## SYMBOLS

$\odot$	Mean longitude of the Sun
$\lrcorner$	Mean longitude of the Moon
$\Omega$	Longitude of ascending node
$\Upsilon$	First point of Aries
+	Symbol of northern latitude or declination, and of westerly longitude and hour angle
-	Symbol of southern latitude or declination, and of easterly longitude and hour angle
[ ]	Symbol of summation; also used to enclose a factor given as a logarithm

# EXPLANATION

## THE CALENDAR

A calendar is a method of combining days into periods adapted to the purposes of civil life and religious observances, or to the requirements of scientific precision, such as weeks, months and years. Three of the periods used in calendars, namely days, months and years, are based on those astronomical periods that have the greatest importance for the conditions of human life. Other measures of time, such as the week and the subdivisions of the day, are artificial.

The complexity of calendars is due mainly to the incommensurability of the astronomical periods on which they are based. The supply of light by the two great luminaries is governed by the periods known to astronomers as the solar day and the synodic month, while the return of the seasons depends on the tropical year. The length of the synodic month at the present time (1935) is 29·5305879 days, while that of the tropical year is 365·24219 days, each period being subject to an uncertainty of about one unit in the last figure given. Both periods are slowly decreasing, the synodic month or lunation by about three and a half units in the last figure every century, and the year by about one and a third units in the last figure every century.\* From the lengths of these two periods we find that the number of lunations in a tropical year is 12·3682668, decreasing by about three units in the last figure every century. The changes in the lengths of these periods are of little importance in the study of calendars.

*Egyptian Calendar.*—The Egyptian year from an extremely remote date consisted of 12 months of 30 days each, followed by 5 days called in Greek *ἐπαγόμεναι* or “added”, making 365 days altogether. The 30-day period is obviously based on the lunation, so that the calendar must at some date have been governed by the Moon, while its primitive connection with the solar year is proved by its division into three seasons—Flood time, Seed time, Harvest time—each containing four months, which in hieroglyphics are always designated by their place in the season to which they were supposed to belong. But before the earliest times known to us, all attempt to equate the calendar month to the phases of the Moon or the calendar seasons to the natural seasons had been abandoned, and the beginning of the Egyptian year and of the calendar seasons gradually retrograded, returning to its place in the tropical year in 1505 tropical or 1506 Egyptian years. The Egyptians, however, used to check the relation of the calendar to the natural year, not by the solstices and equinoxes, but by the heliacal rising of Sirius, which, according to Herr Schoch’s determination,† returned in the latitude of Memphis at a mean interval of 365·2507 days. The Egyptians, taking the length of the natural year as 365·25 days, formed a cycle of 1461 calendar years which they equated to 1460 natural years, and which was known by the name of the Sothic or dog-star cycle. In the absence of an accurate historical chronology and of a continuous record of years a cycle of this length had a purely theoretical importance.

The Egyptian calendar was, up to the time of Julius Cæsar’s reform of the Roman calendar in 46 B.C., the only civil calendar in which the length of each month and of each year was fixed by rule, instead of being determined by the discretion of

\* See the figures in Schoch’s *Neubearbeitung der Syzygientafeln von Oppolzer*, Mitteilungen des Astronomischen Recheninstituts Berlin-Dahlem, Band 2, Nr. 2 (1928), II. Other recent determinations are in close agreement with Schoch’s.

† *Die Länge der Sothisperioden beträgt 1456 Jahre*, Selbstverlag, Berlin-Steglitz, 1928.

officials or by direct observation. If the number of years between two astronomical observations, dated by the Egyptian calendar, was known, the exact number of days could be determined by a simple calculation. No such comparison could be made between dates referred to any other civil calendar unless the computer had access to a record showing the number of days that had actually been assigned to each month and the number of months that had actually been assigned to each year. It is true that the Egyptians did not use a continuous era, but were content to number the years of each reign separately, so that there was a difficulty in identifying a particular year, but the astronomers of the Ptolemaic age rectified this by the introduction of eras. The simplicity and regularity of the Egyptian calendar commended it to astronomers, who found it excellently adapted to the construction of tables that could be readily applied and used even for a remote past or for a distant future without any fear that the system by which time was reckoned in the tables might not coincide with the system in actual use. In the second century B.C. we find Chaldean observations, sometimes nearly six centuries old, reduced to the Egyptian calendar in the works of Hipparchus, who observed not in Egypt but at Rhodes, and cited from him by the Egyptian Ptolemy in the second century of our era; we also find in the second century B.C. an Athenian observation of 432 B.C. reduced to the Egyptian calendar on an inscription found at Miletus, which appears to represent the work of the astronomer Epigenes.

Each Egyptian month had its proper festival. These festivals were finally fixed about 1200 B.C., and in Aramaic and Greek texts from the fifth century B.C. onwards the Egyptian months bear names based on the monthly festivals.

An attempt by Ptolemy Euergetes in 238 B.C. to introduce a sixth *ἐταγομένη* once in four years failed, but a renewed attempt under Augustus (26–23 B.C.) was more successful. An additional day was inserted at the close of the Egyptian year 23–22 B.C. on August 29 of what we call the Julian calendar, and at the close of every fourth year afterwards, so that the reformed or Alexandrian year began on August 30 of the Julian calendar in the year preceding a Julian leap year and on August 29 in all other years. The effect of this reform was to keep each Egyptian month fixed to the place in the natural year which it happened to occupy under the old calendar in the years 26–22 B.C. But the old calendar was not easily suppressed, and we find the two used side by side till A.D. 238 at least. The old calendar was probably the more popular, and was preferred by astronomers and astrologers. Ptolemy always used it, except in his treatise on annual phenomena, for which the new calendar was obviously more convenient. Theon in the fourth century A.D., though mentioning the old calendar, habitually used the new.

The old Egyptian calendar was adopted by the Persians, perhaps about 500 B.C., in a form that cannot now be accurately restored, and survives in a slightly modified form in the Armenian calendar, the three first months of the old Egyptian year corresponding exactly with the three last months of the Armenian year. These are followed in the Armenian calendar by the five additional days, so that for the remainder of the year the Armenian months begin five days later than those of the old Egyptian calendar. The Alexandrian calendar is still the calendar of Abyssinia and of the Coptic church, and is used for agricultural purposes in Egypt and other parts of northern Africa.

*Babylonian Calendar.*—The main principles of the Babylonian calendar became fixed in the latter half of the third millennium before Christ. The year began in the spring with the month *Nisanu*. It contained ordinarily twelve months, the beginnings of which were fixed by observation of the lunar crescent. In this calendar,

as in all lunar calendars except the Mohammedan, one of the months was repeated when necessary, in order to keep each month fixed to a definite season in the year. At Babylon the month so repeated was most commonly the last month *Addaru*, but not infrequently the sixth month *Ululu*, and very occasionally some other month. The intercalary month was inserted at very irregular intervals, the known intervals between one intercalation and the next varying from six months to six years. It would appear that from the accession of Nabonassar in 747 B.C. a record was kept of the observations in each month and of the number of days that were assigned to each month. This made it possible to define the exact interval between observations and provided the means for a precise determination of astronomical periods, especially those which affected the times and magnitudes of lunar eclipses. The oldest precise determination of which we have any knowledge was the eclipse period or *saros* in which 223 lunations were taken as equal to  $6585\frac{1}{3}$  days. The correct astronomical length of 223 lunations was 6585.323 days, so that the error would amount to one day in about 1800 years. This period must have been known early in the sixth century B.C. The *saros* is independent of the length of the tropical year, but Geminus and Ptolemy state that the motion of the Sun in longitude in the *saros* period was taken as equal to 18 revolutions plus  $10\frac{3}{4}^\circ$ . The correct time for the Sun's longitude to increase by this amount was 6585.19 days, so that the assumed length of the natural year involved an error of about 0.14 day in 18 years.

From 529 to 504 B.C. an octaeteris or 8-year cycle was in use at Babylon. In this the length of each month was still determined by observation of the crescent, but the intercalary months occupied fixed places in the cycle and each cycle of 8 years was made to contain 99 months. The effect of this was to make the mean length of eight years amount to 2923.53 days as compared with a correct duration of 2921.94 days and the received value of 2922 days. It is not surprising that this cycle was soon laid aside and arbitrary intercalation resumed. If we may accept Schnabel's dates\* for Naburianos and Cidenas there was a steady improvement in the determination of astronomical constants in the next age. Naburianos about 500 B.C. found for the synodic month a length of 29.530614 days as compared with the correct value of 29.530596 days, and for the year 365.2609 days as compared with the correct value of 365.2425 days for the tropical year. But since the length of the year was derived from the inequalities that it produced in the length of the month, it would be more correct to compare it with the anomalistic year, which had a duration of 365.2598 days. Cidenas about 383 B.C. determined the length of the synodic month as 29.530594 days. He also determined the length of the tropical year as 365.236 days. In 383 B.C. a 19-year cycle of intercalations was introduced at Babylon, which continued in use as long as a Babylonian calendar can be traced. This provided for 7 intercalary months occupying fixed places in each cycle of 19 years, so that 19 years were equated to 235 lunations. The beginning of each month continued to be determined by observation of the lunar crescent. An astronomical 19-year cycle had, as will be seen, been published by Meton at Athens in 432 B.C. The effect of the Babylonian 19-year cycle is to make the mean year consist of 12.36842 lunations, and to make the mean calendar year consist of 365.2468 days, an excess of 0.0043 over the correct value.† Cidenas' value for the mean synodic month is retained in the modern Jewish calendar, as is the system of seven intercalations in 19 years, so that the Jewish calendar continues to imply a length of 365.2468 days for the year.

*Greek Calendars.*—All Greek calendars were lunar until the Roman period. Each community had a separate calendar. Bischoff has succeeded in putting together more or less complete lists of months in about a hundred Greek calendars.\* There was great variety in the season when the year began in different calendars, but each month was kept roughly to one season of the year by the insertion of a thirteenth or intercalary month when required. In some calendars this was done by repeating the sixth month, in some by repeating the twelfth month; but in a few the intercalary month occupied other positions, and at Athens there are four instances preserved on inscriptions where an intercalation was made at an exceptional place in the year, and it is probable that the same happened elsewhere from time to time. Not only the intercalation of months, but also the regulation of the length of each month, appears to have been always in the hands of the public authorities, and if, as time advanced, they paid increasing respect to astronomical calendars, there is no evidence that any astronomical calendar ever acquired legal validity. The beginning of the Attic civil year is known to have fluctuated by 53 days as compared with the natural year during the Peloponnesian war.† We have less definite information as to the extent to which the beginning of the civil month was permitted to depart from the New Moon, but Aristophanes in *The Clouds*, acted in 423 B.C., makes the Moon complain that the days are not being kept correctly according to the Moon.

During the fifth century B.C. the Athenians had a senatorial or financial year, which was independent of the ordinary civil year and of the Moon. The council of 500 was divided into ten boards or prytanies, each of which functioned for the tenth part of the senatorial year. Meritt has shown that this year was a solar year of approximately 365½ days, beginning about July 6 of the Julian calendar, though the actual length could be varied at the discretion of the competent authorities. Inscriptions dealing with public accounts regularly date by the days of the different prytanies, though the year consisting of lunar months regulated the admission of magistrates, the celebration of festivals, and the proceedings of courts and assemblies. The financial year was, however, accommodated to the lunar calendar in or about 409 B.C.

The Macedonian calendar, which was of the Greek type, became current in western Asia as a result of Alexander's conquests, and even competed with the native calendar in Egypt. But in the Roman period the Greek calendars of Asia became purely solar calendars.

From the sixth century B.C. onwards the Greek astronomers, beginning with Cleostratus of Tenedos, framed a number of cycles, in which each month and year were given exact lengths dependent on their places in the cycle, and the attempt was made, so far as could be done without making the cycle too cumbrous, to maintain both for the mean month and for the mean year their correct astronomical values. It was an easy matter to compute the interval from one date to another in a calendar regulated by cycle, which was independent of the discretion of city governments. The original intention may have been merely to facilitate the determination of the age of the Moon and the season of the year, but the Metonic and Callippic cycles at least came to be used for dating astronomical observations.

The cycle invented by Cleostratus was an *octaeteris* or 8-year cycle and it probably dates from the time when an 8-year cycle was in use at Babylon. It made 8 years equal to 99 lunations and to 2922 days. As 99 lunations contain 2923·53 days, this

form of the octaeteris would, if persisted in, have led rapidly to a large error in the tabular date of New Moon. Geminus records successive improvements in this calendar without mentioning their dates. The first was to add 3 days every 16 years, thus making 16 years equal to 198 lunations and to 5847 days. As 16 years should be 5843.88 days and 198 lunations should be 5847.06 days, the increased accuracy in the month was purchased at the expense of a large error in the year. Finally, we are told that a month of 30 days was omitted once every 160 years, so that 160 years were made equal to 1979 lunations and to 58440 days. As the correct length of 160 years was 58438.8 days and of 1979 lunations 58441.0 days, the error in each was only about one day in 160 years.

Long before the octaeteris can have reached its final form the Athenian astronomer Meton published his 19-year cycle, which began on June 27, 432 B.C., this being, according to Meton, the day of the summer solstice and the 13th day of the lunar month Scirophorion. The months in this calendar had the same names as the Attic months, and the intercalation was made as in the Attic calendar by repeating the sixth month, Poseideon. But the length of each year and month was made dependent on its place in the cycle, which also governed intercalation. In this cycle 19 years were made equal to 235 months and to 6940 days; the correct length of 235 months was 6939.69 days, and of 19 tropical years 6939.61 days, but Meton may have been aware of Naburianos' value for the year, which made 19 years equal to 6939.95 days.

An attempt to improve on this calendar was made by Callippus, who gave to the year its generally received value of 365.25 days, and combined four 19-year periods to form a period of 76 years, which he made one day shorter than four Metonic periods, so that it consisted of 27759 days, which he equated to 940 lunations. This made 19 years equal to 235 lunations and to 6939.75 days, a great improvement on Meton in respect both of the synodic month and of the tropical year. Callippus' first cycle was made to begin in 330 B.C., when the summer solstice and New Moon coincided. It appears to have been used by astronomers as a means of dating for two centuries.

The last of the Greek astronomical cycles was that devised by Hipparchus, who proposed to omit one day from every fourth Callippic cycle, thus making a cycle of 304 years equal to 3760 lunations and to 111035 days. This would give a length of 29.530585 days to the lunar month and of 365.24671 days to the year. The former approximates very closely to Cidenas' value, which Hipparchus had adopted; the latter is almost identical with the value assumed by the 19-year cycle in use at Babylon in Hipparchus' time and is still nearer to the value 365.24667, which he himself deduced from observations. Neither Hipparchus himself nor anyone else appears to have made use of this cycle.

The lunar calendar was not suitable for determining the proper season for agricultural operations. In order to know the exact time of the year the Greek farmer used to observe the annual risings and settings of certain of the fixed stars, and to note the solstices and the comings of birds. Hesiod gives some information in his *Works and Days* on this subject. In the fifth century B.C. *paraepgmata* showing the annual dates of the principal risings and settings and the weather that might be expected to follow them began to be constructed, and the published calendars of Meton and Euctemon included these. Fragments of Milesian *paraepgmata* of the second century B.C. are preserved. They are arranged according to the solar year, with a hole against each day and instructions, sadly mutilated, for showing the lunar month and day by means of movable pegs.

*Roman Calendar.*—The Roman calendar, which is now used throughout the whole world, had its origin in the local calendar of the city of Rome. It is generally stated by our ancient authorities that the year of Romulus consisted of 304 days divided into 10 months beginning with March, and that Numa introduced a lunar year and added January and February. It may be regarded as certain that the Roman months were originally lunar, and throughout the republican period the normal length of the year remained 355 days, exceeding 12 lunations by 0.63 days. This small excess could have been compensated by making the intercalary month consist sometimes of 27 and sometimes of 28 days. Such a month was in fact inserted, when it was considered necessary, after February 23. But at least in historical times the five last days of February were not repeated after the close of the intercalary month. As the days at Rome were generally enumerated in reference to the next following Kalends (1st of month), Nones (5th or 7th of month), or Ides (13th or 15th of month), it is a purely academic question whether the five days preceding the Kalends of March were part of February or part of the intercalary month. Both views can be supported from classical texts. At all events the failure to repeat these five days necessitated a departure of the calendar from the Moon. We do not know when this took place, but, if the eclipse of Ennius is correctly dated in the 350th year of the city, then we have an eclipse of the Sun on June 5 of the Roman calendar as far back as 400 B.C., and we may infer that the calendar had by that date worked free from the Moon. In historical times the months of March, May, Quintilis (July) and October contained 31 days each, the months April, June, Sextilis (August), September, November, December and January 29 days each, while February contained 28 days. In March, May, Quintilis and October the Nones were on the 7th day and the Ides on the 15th; in the other months the Nones were on the 5th day and the Ides on the 13th. The intercalary month was generally inserted in alternate years, but the actual regulation of intercalation was in the hands of the pontifices.

Under the pontificate of Julius Cæsar, who became Pontifex Maximus in 63 B.C., intercalation was neglected with such frequency that the Kalends of January, which had fallen on or about December 13 of the subsequent Julian calendar at the close of 64 B.C., fell on October 13 of that calendar at the close of 47 B.C. In order to restore the months to their normal position in the natural year, Cæsar not only gave the year corresponding to 46 B.C. the usual intercalation of 23 days after February 23, but inserted two additional intercalary months, amounting together to 67 days, between November and December, so that the Kalends of 45 B.C. fell on what is still called January 1 of the Julian Calendar. From that time each month has had its present duration, the sixth day before the Kalends of March being repeated when necessary. The intercalary day came to be called *ante diem bis sextum Kalendas Martias*, or more briefly *bissextum*, whence our word bissextile for leap year.

The revised calendar, in framing which Cæsar had the assistance of the astronomer Sosigenes of Alexandria, adopted for the mean year the value current in Egypt, 365.25 days, three years out of four being given 365 days, and the fourth 366 days. As the calendar year was purely solar, the annual astronomical phenomena were expected to return annually on the same dates, and an almanac showing these dates was published with the new calendar. This rendered unnecessary the observation of these phenomena by farmers, who were now able to orientate themselves in the natural year by means of the new calendar.

Cæsar's edict requiring the intercalary day to be inserted every fourth year was

misunderstood by the pontifices, who reckoned the four years inclusively and intercalated at intervals of three years; in consequence the year 8 B.C. began three days too late. Augustus rectified this error by omitting all intercalations till A.D. 8, from which date the Julian calendar was observed strictly till the reform of Pope Gregory XIII in A.D. 1582. As the first year of the new calendar (45 B.C.) was a bissextile or leap year, it follows that years of the Christian era divisible by four are leap years. The name Quintilis was changed to July (Julius) in 44 B.C. in honour of Julius Cæsar and the name Sextilis was changed to August (Augustus) in 8 B.C. in honour of Augustus Cæsar; later attempts to change the names of months were unsuccessful.

The position of the Roman intercalary month agrees with the ancient tradition that March was originally regarded as the first month of the year. The years were commonly designated by the names of the consuls, so that the designation changed on the day when the new consuls along with the other curule magistrates entered office. After considerable fluctuation the date of entering office was fixed as March 15 about 222 B.C., but was transferred to January 1 in 153 B.C., and was never afterwards changed. In this way January became the first month of the official year. In the eastern provinces under the empire the years were often reckoned from the accession of the reigning emperor, his second year being made to begin on the first new year's day after his accession. The day which served as new year's day for this purpose varied from district to district. The January new year was in fact confined to western Europe.

*Indictions.*—The Cycle of the Indiction, a non-astronomical cycle of 15 years, is first mentioned in receipts for taxes collected in Egypt in A.D. 303 in respect of profits or produce of the fifth indiction (A.D. 301–302). It probably takes its origin in a provincial census for taxation following Diocletian's reconquest of Egypt in 297, a new census being taken every fifteen years. Each year in this cycle was regarded as a separate indiction. The earliest indictions appear to be reckoned from the Alexandrian new year, which fell generally on August 29, but, so long as it was strictly a financial year, the date from which the indiction was reckoned was frequently shifted according to the exigencies of public policy. The use of this cycle spread afterwards to other countries, where it was adopted as a means of designating years without special reference to public finance. There are various forms of the cycle, differing as to the day of their commencement. The Greek or Constantinopolitan indiction changed on September 1; the Roman indiction, which changes on December 25 or January 1, is rarely found before the 11th century.

To find the indiction corresponding to any year of the Christian era add 3 to the year and divide the sum by 15; the remainder (or 15 if exactly divisible) is the Roman indiction or the Greek indiction up to the day of change; if the indiction beginning in any year is required, 4 instead of 3 must be added.

*Jewish Calendar.*—The ancient Jewish calendar was of the normal lunar type with twelve months, each of which began with the first visibility of the crescent Moon. Intercalation was performed when necessary by repeating the twelfth month, which in post-exilic times was known as Adar. The responsibility for intercalation rested with the public authorities, and in the early centuries of the Christian era was vested in the Sanhedrin, regard being had to the progress of crops and stock with a view to the proper celebration of the Passover, which fell in the first month. The months are most commonly designated in the Old Testament and Apocrypha by their numerical order, which is always counted from the spring month of Abib or Nisan. Originally the months had the same names as are found on Phœnician

inscriptions, but in post-exilic times these were replaced by the Babylonian names. There are, however, in the Hebrew Scriptures references to the end of the year that would imply an autumn new year. This would be the agricultural year beginning with the autumn ploughing and ending with the vintage. In the book of Nehemiah regnal years are reckoned from the autumn month of Tishri, though everywhere else in the Old Testament they are reckoned from Abib or Nisan. Both beginnings of the year seem to be found in the Apocrypha, although as has been seen the months are always numbered from Nisan. In the last centuries before the Christian era the autumn new year was well established in Syria, and the reckoning of the year from Tishri is probably due to Syrian influence.

The papyri belonging to the Jewish colony at Elephantine in Southern Egypt in the fifth century B.C. show that at that place the beginning of the month was reckoned from the first evening when mean sunset or 6 p.m. followed mean new moon, so that we have a calendar determined by astronomical calculation, not by astronomical observation. There is, however, no reason to suppose that the Elephantine custom extended to Palestine. At Elephantine as in Palestine intercalation appears to have been irregular. The regnal years are reckoned from Nisan although the papyri are contemporary with Nehemiah who reckons such years from Tishri.

The empirical calendar has been superseded by one based on fixed rules, in which nothing is left to observation or discretion. The date when the modern calendar was designed is unknown, but it is commonly assigned to the fourth century of our era. This calendar is based on a rigorous determination of the mean new moon of Tishri, in which Cidenas' value for the mean lunation is used. Intercalation is governed by a 19-year cycle, and so the mean duration of the calendar year is the same as that which was adopted at Babylon in 383 B.C. The actual beginning of the calendar Tishri is obtained from the mean new moon by complicated rules which are designed to prevent certain solemn days from falling on inconvenient days of the week. The effect of these rules is that a common year may contain 353, 354 or 355 days, and an embolismic or leap year 383, 384 or 385 days. Ten of the months have fixed durations, the other two varying according to the requisite length of the year. The intercalary month always contains 30 days. It is placed next before the month Adar whose name and place it usurps; Adar itself becomes the second Adar or Veadar, and retains its normal length of 29 days.

The Jews now employ an era of the creation, whose epoch is taken as October 7 3761 B.C.

*The Week.*—In Assyria in the seventh century B.C. there was a general abstinence from work on the 7th, 14th, 19th, 21st and 28th days of each month, and these days, along with certain other days, were observed by a general abstinence from work in the first month of the year in Assyria in the tenth century B.C. It is not yet possible to state how old or how widespread this practice of abstaining from work on each seventh day was. The Mosaic law enjoined a general abstinence from work on each seventh day, which was called the Sabbath. It has been suggested that the Hebrew periods of seven days may, like the Assyrian, have been reckoned originally from the beginning of each month, but this is only surmise. When we come upon clear evidence, the Hebrew period of seven days was reckoned independently of the month and in fact of all astronomical periods. From the Jewish church it has passed into the Christian, in which special veneration is paid to the first day of the week, or Lord's Day (*κυριακή*, Dominica, dimanche).

Quite independently of the Jews there arose not long before the Christian era a group of astrological periods of seven hours, seven days, seven months and seven years respectively. According to Cassius Dio the astrological period of seven days was of Egyptian origin, and as it was based on the Egyptian practice of dividing the day and night separately into twelve hours, there is every reason to believe that his statement is correct. The seven planets, including the Sun and Moon, were arranged in the order of their supposed distance from the Earth, according to the theory that was current in Hellenistic Egypt:—Saturn, Jupiter, Mars, Sun, Venus, Mercury, Moon. Each of these in turn was supposed to control one hour, and the planet that controlled the first hour of the day, month or year was regarded as the regent of that day, month or year. A day of 24 hours, therefore, included three periods of seven hours and three hours of a fourth period, and the regent of each day would be removed by three places in the order of the planets from the regent of the preceding day. There was thus obtained the following series of regents of the days:—Saturn, Sun, Moon, Mars, Mercury, Jupiter, Venus. These planetary days acquired a rapid and world wide popularity, while the planetary hours, months and years interested none but astrologers. The first reference to a planetary day is in a poem by Tibullus written between 30 and 26 B.C. Although the planetary week began originally with the day of Saturn, the day of the Sun soon came to be more commonly regarded as the first of the week, partly, no doubt, because it coincided with the first day of the Jewish week. But the planetary hours continued to be enumerated from the hour of Saturn. Although there has been universal agreement in the attribution of individual days to individual planets, there has been no such agreement in the attribution of nights and hours. In the Teutonic languages the names Tiu, Woden, Thor and Freya of the Teutonic divinities with whom Mars, Mercury, Jupiter and Venus were respectively identified have taken the place of their Roman counterparts. But, while the planetary names for the days of the week have established themselves throughout western Europe, they are not in use among oriental Christians.

*Ecclesiastical Calendar.*—The Christian church has continued the Jewish festival of Passover, which as a Christian festival has received in our language the name of Easter. In Greek and Latin the identity was maintained by the use of the same name Pascha. According to Christian teaching the sacrifice of the Passover, which had been celebrated on Nisan 14, was fulfilled in the sacrifice of Christ. According to the Mosaic law the sacrifice of the Passover on Nisan 14 had been followed by a feast of seven days lasting till Nisan 21. The Christian churches in Asia Minor largely retained the Mosaic rule and celebrated Easter on the Jewish Nisan 14 without regard to the day of the week. With a few unimportant exceptions the rest of Christendom celebrated Easter on a Sunday, selected so as to fall within the passover week. It is found that when the customs hardened, the Church of Rome observed the Sunday which was believed to fall not earlier than the 16th nor later than the 22nd day of the Moon, that of Alexandria the Sunday which was believed to fall not earlier than the 15th nor later than the 21st day of the Moon, while the British churches observed the Sunday which was believed to fall not earlier than the 14th nor later than the 20th day of the Moon. There was heated controversy between the churches of Rome and of Asia Minor on this subject in the second century. In the third century Christian churches, refusing to accept the authority of the Jewish councils to decide which month was to be regarded as Nisan or on which day it was to begin, began to construct tables of their own for computing the 14th day of the Easter month and the date of Easter. Two cycles dating from that century obtained a wide currency—the Roman cycle of 84 years and the Alexandrian of 19 years.

The Alexandrian cycle was simplicity itself. March 21 of the Julian calendar was regarded as the date of the vernal equinox, and all Alexandrian, and therefore all Julian years, were treated as of equal duration. The cycle was made to begin in the year that placed a new moon on the Alexandrian new year's day, August 29-30, and, in consequence, gave April 5 as the date of the 14th day of the Easter moon. This 14th day was placed 11 days earlier in each year than in the preceding year when this could be done consistently with its not falling before March 21. Where this was impossible, it was placed 19 days later than in the preceding year. Finally, in passing from the 19th to the 1st year of the cycle, an interval of 12 days instead of 11 was allowed, so as to bring the 14th day in the 1st year of the next cycle back to April 5. Easter day was the first Sunday after the 14th day of the Easter moon. This calendar assumed the same mean length of the year and the lunar month as the Callippic cycle and was therefore subject to the same errors. Its authors can hardly have expected it to remain uncorrected for many cycles. As a cycle it was subject to the inconvenience that it took 532 years for the whole series of Easter dates to recur.

The Roman cycle of 84 years was made to begin in a year in which a new moon fell on the Roman new year's day, January 1, and also on the Sabbath (Saturday). It made 84 tropical years equal to 1039 lunations and to 30681 days. The correct length of 84 tropical years was 30680.36 days, and of 1039 lunations 30682.29 days, so that the equinox fell 0.64 days earlier as compared with the assumed date every 84 years, and the new moons 1.29 days later as compared with the assumed dates in the same interval. The error in the length of the year was the same as in the Alexandrian cycle, but the error in the length of the lunation was nearly five times as great as in the Alexandrian cycle and was in the opposite direction. A further difference arose from the facts that the Roman rule treated the 16th, while the Alexandrian treated the 15th day of the moon as the earliest date for Easter, that the Roman rule accepted a 14th day of the month even if it fell before the equinox, so long as the resultant Easter fell after the equinox, and that the Roman rule regarded April 21 as the latest date for Easter, while the Alexandrian rule permitted it to fall as late as April 25. During the fourth and the first half of the fifth centuries differences between the two calendars were often, but not always, settled as they arose by agreement between the Roman pope and the patriarch of Alexandria, but long before the end of the fourth century it had come to be the practice that it was always the Roman Church that gave way.

In 325 the General Council of Nice dealt with the date of Easter. Its decision is expressed in its epistle to the Church of Alexandria:—"We also send you the good news concerning the unanimous consent of all in reference to the celebration of the most solemn feast of Easter, for this difference also has been made up by the assistance of your prayers, so that all the brethren in the East, who formerly celebrated this festival at the same time as the Jews, will in future conform to the Romans and to us and to all who have from of old kept Easter with us."

A cycle of 532 years based on the 19-year cycle was composed by Victorius in A.D. 457 at the request of the Pope. It agreed with the Alexandrian cycle in the mean lengths of the year and month, but there were minor differences, which from time to time gave different dates for Easter. The papal Curia did not hold itself bound to any of the three cycles, and local usage varied. The last year in which the 84-year cycle was followed in Rome against both the Alexandrian and the Victorian cycles was A.D. 501.

The Alexandrian cycle found a capable exponent at Rome in the person of

Dionysius Exiguus about A.D. 530. He constructed an Easter table extending from A.D. 532 to A.D. 626, in which he introduced for the first time the years of the Christian era, which was adopted from him by Bede and from Bede by western Christendom generally. The only part of the furniture of a late mediæval Easter table that was not used by Dionysius was the solar cycle, which would appear to have been first used by Maximus Confessor in Africa in A.D. 641.

The British and Irish churches continued to use the 84-year cycle in a form that permitted Easter to fall as early as the 14th day of the moon and gave March 25 as the earliest possible date of Easter. But at the Synod of Whitby in A.D. 664 King Oswy of Northumbria under the influence of Wilfrid decided to adopt the Dionysiac system. The decision was accepted by the other English communities, and Bede, the Northumbrian church father, was brought up to the use of the Dionysiac system. His *De temporum ratione*, written in 725, included not merely an exposition, but an Easter table for the 532 years from A.D. 532 to 1063, and rapidly became the standard treatise on the subject. Before the end of the eighth century the 84-year cycle had been abandoned by the last of the British churches, and even in France the Victorian cycle had given way to the Alexandrian.

*Gregorian Calendar.*—As the centuries advanced, the gradual shifting of the calendar dates of the seasons did not escape attention. In fact in 11,000 years or so January would have ceased to be a winter month. Dante\* refers to this as follows:—

Ma prima che gennaio tutto si sverni,  
per la centesima ch'è laggiù negletta.

"But, ere that January be all unwintered by that hundredth part neglected upon earth."

The hundredth part is here the difference between the mean calendar year of 365·25 days and a supposed tropical year of 365·24 days.

The defect of the calendar in the sixteenth century showed itself mainly in its effect on the date of Easter, since the tables in use placed both the vernal equinox and the Easter full moon, or more exactly the 14th day of the Easter moon, later than their true dates. Accordingly in 1582 Pope Gregory XIII published a bull instituting a revised calendar. He considered it desirable to restore the vernal equinox to the position assigned to it in the Easter tables, namely March 21, and accordingly ordained that the day after 1582 October 4 should be called October 15. In future the intercalary day, which in the Julian calendar was inserted once every four years, was to be dropped in those centurial years that were not divisible by 400. Thus 1600 and 2000 were to be leap years, but not 1700, 1800 and 1900. The effect of this was to make the mean length of the year 365·2425 days, a duration that was correct about the third century B.C., but is slightly in excess of the present length of the year. The reform has the merit of treating the simple Julian system as correct for one or two centuries at a time and making corrections in centurial years only. The same simplicity marked the new treatment of the lunar month. The dates of the Easter full moons were put back three days, or advanced seven days if we include the reduction to the Gregorian year. If this involved placing the 14th day of the Easter moon later than April 19, the full moon of the previous lunation was accepted, so that the date of the Easter moon was put back 23 days in the calendar. If the shift involved placing the 14th day of the moon on April 19 it was placed on April 18 instead.

A similar shift was to be made in centurial years, if required. There was to

\* *Paradiso*, XXVII, 142, 143.

be a forward shift of one day in every centurial year that was not a leap year, and a backward shift of one day in 8 out of every 25 centurial years. This backward shift was to be made for the first time in 1800, then at seven intervals of 300 years and one of 400 years, and so on. If a backward and forward shift were due in the same centurial year the dates of the full moons were to be the same in each year of the 19-year cycle as in the preceding century. The calendar was to be worked as if the dates of full moon for each year of the cycle were to range from March 21 to April 19 inclusive, except that all full moons that should have fallen on April 19 were to be put back to April 18, and, whenever this was done, a full moon that was due for April 18 in another year of the cycle was to be put back to April 17. The object of this exception was to retain April 18 as the last possible date for the Easter full moon.

But transferences of full moon dates under this exception do not affect the subsequent dates of full moon for the particular place in the 19-year cycle. Thus the full moon of the 14th year of the cycle, which in the unreformed calendar had stood on April 12, was placed on April 18 after the reform and not on April 19, but the forward shift of one day in 1700 brought it to March 21 as if it had been on April 19. Similarly the full moon of the 6th year was shifted in 1700 from April 17 to April 18, but in 1900 it remained at April 18 instead of being shifted to April 19. The result of this was that the full moon of the 17th year, which should have been shifted to April 18 in 1900, remained at April 17. Its next forward shift will be to April 18, taking the place of April 19, and then to March 21. The effect of this exception is that every full moon date gets two turns either on April 17 or on April 18, so that, although the total range of full moon dates is only 29 days inclusive, it takes 30 forward shifts to bring the full moons back to their former positions.

Altogether 5,700,000 Gregorian years are made equal to 70,499,183 lunations and to 2,081,882,250 days, so that the mean length of the lunation is taken as 29.5305869 days, a value that is in error by the millionth part of a day at the present moment, but will be correct in the course of 300 years. Since 400 Gregorian years contain 146,097 days or 20,871 weeks, the days of the week recur on the same days of the year every 400 years, and there should therefore be a recurrence not only of Easter full moons, but also of Easter Sundays, after the lapse of a complete cycle of 5,700,000 years.

This calendar combines the merits of extreme accuracy in its mean values with extreme simplicity in its application, since for a period varying from one to three complete centuries it is able to determine the date of full moon as if all calendar years were of equal duration and as if the 19-year cycle were exactly applicable, so that a table as simple as that used for the unreformed calendar will hold good for that length of time. The calendar is independent of differences of meridian. It makes the moon full on one particular day for the whole world without specifying any particular moment. The astronomical Full Moon takes place at a particular moment, which will fall on different calendar days according to the meridian selected, being more often than not on a different calendar day in Australia and in Canada. The time of astronomical Full Moon is also affected by inequalities in the motion of the Sun and Moon. The calendar full moon is not affected by these inequalities, just as the time used in civil life is not affected by inequalities in the length of the day. It follows, therefore, that the simple tables of the Prayer Book and the elaborate tables used in H. M. Nautical Almanac Office must occasionally differ in their final results.

The Gregorian calendar was adopted in Italy, France, Spain, Portugal and

Poland in 1582, by most of the German Roman Catholic states and by Holland and Flanders in 1583, and by Hungary in 1587. The adoption in Switzerland was gradual; it began in 1582 and was completed in 1812. The German and Dutch Protestant states generally, along with Denmark, adopted it in 1700, the British dominions in 1752, Sweden in 1753, and Japan in 1873. It became the official calendar of China and Albania in 1912, Bulgaria in 1916, Soviet Russia in 1918, Rumania and Greece in 1924, and Turkey in 1927. The rules for Easter have not, however, been adopted by those oriental churches that are not subject to the papacy.

The German Protestants, in adopting the Gregorian calendar, did not adopt the Gregorian rules for the computation of Easter, but enacted that both the date of the equinox and the date of the Easter full moon should be determined astronomically with the Rudolfine tables and the meridian of Uranienborg (in the island of Hveen between Denmark and Sweden). This astronomically determined Easter was used by the German Protestants from 1700 to 1776 and by the Swedes from 1740 to 1844.

In the British dominions the change of calendar was effected by giving the name September 14 to the day after September 2 in 1752. The difference between the Julian and Gregorian calendars, which was 10 days in 1582, is now 13 days, but the Alexandrian and Gregorian Easters may be as much as 5 weeks apart.

It is provided by the Easter Act, 1928, that "Easter-day shall, in the calendar year next but one after the commencement of this Act and in all subsequent years, be the first Sunday after the second Saturday in April." The Act is to commence and come into operation on a date to be fixed by Order in Council, but no such Order in Council is to be made until a draft order has been approved by resolution by both Houses of Parliament "either without modification or with such modifications to which both Houses agree." Before making such draft order, regard is to be had to any opinion officially expressed by any Church or other Christian body. The Act is to extend to the United Kingdom, the Isle of Man, and the Channel Islands, and may be extended by Order in Council to any other part of His Majesty's dominions except British India, the Dominion of Canada, the Commonwealth of Australia (including Papua and Norfolk Island), the Dominion of New Zealand, the Union of South Africa, the Irish Free State and Newfoundland. The effect of these provisions is to expedite procedure, but to postpone final decision on the change in the calendar.

*Differences of Style.*—The Christian era invented by Dionysius Exiguus and popularised by Bede has been adopted at different times and in different countries with different initial days for the year. The most common initial dates have been December 25, January 1, March 1 and March 25. These different reckonings of the year were known as *styles*. Thus in Italy down to the eighteenth century the years of the Christian era began in the Venetian style on March 1, in the Pisan style on the preceding March 25, and in the Florentine style on the following March 25, while at Rome different styles were used for different purposes. In England the Nativity style beginning on December 25 was superseded in the fourteenth century by the Annunciation style beginning on March 25, but the Circumcision style beginning on January 1 was substituted in 1752 by the Act that introduced the Gregorian calendar. In Scotland the year had begun officially on January 1 since 1600. The names old style and new style were, however, used to distinguish not the different dates for the beginning of the year, but the Julian and Gregorian calendars, each of which has been used with different initial dates.

In the classical languages the numerical designation of years is always by ordinal numbers, so that the Christian era begins with the beginning of the year 1 or of the first year. The year immediately preceding is the year 1 B.C. or the first year before Christ. The year before 1 is styled 0 by astronomers, and the preceding year is -1, corresponding to 2 B.C. in the usage of historians. Therefore in converting years B.C. into astronomical dates it is necessary to subtract 1 and to prefix the minus sign. In converting negative astronomical dates into years B.C. it is necessary to remove the minus sign and to add 1 to the number of the year.

*Sunday Letter, Solar Cycle, Golden Number, Epact.*—The Roman calendar makers were accustomed to place the letters A, B, C, D, E, F, G and H in rotation against the days of the year. At first these letters referred to the Roman market week of eight days. Then if the first market day in any year were known, as for instance January 5, the letter E standing against that day would indicate all the market days in the year. The next device was to use the same series ending with G to indicate the seven days of the planetary week, which coincides in practice, though not in origin, with the Christian week. The letter that stands against the Sundays in any year is known as the *Sunday Letter* or *Dominical Letter* of that year. Since no letter is placed against the intercalary day, it follows that in leap years the Sunday Letter retrogrades by one place at the date of the intercalation. Thus in 1936 E will be the Sunday Letter in January and February, and D from March onwards. As the ordinary year contains 52 weeks and 1 day, the Sunday Letter also retrogrades one place at the beginning of each year. The series of letters has always been made to begin on January 1 as in the pre-Christian Fasti, whatever day may have been adopted for the beginning of the civil year.

In the Julian calendar the days of the year recurred on the same days of the week in  $7 \times 4$  years, thus giving rise to the so-called *Solar Cycle* of 28 years, which could be used for the purpose of finding the day of the week for any day in a known year. The years of this cycle are commonly shown in almanacs, but it has been very little used in practice. There is mention in the Talmud of a 28-year cycle, at the close of which the vernal equinox, supposed to recur at intervals of  $365\frac{1}{4}$  days exactly, would return both to the same planetary hour and to the same day of the week. The beginning of each 28-year cycle is still observed by the Jews, but has ceased to have any calendrical or astronomical significance. As has been seen above the solar cycle for correlating the week with the Julian calendar appears to have been first used by Maximus Confessor in A.D. 641. Supposed older works which mention this cycle have probably been misdated.

The tables for finding Easter according to the Alexandrian calendar tabulated the days from March 21 to April 18 and placed against each day the number of the year in the 19-year cycle in which the Easter full moon would fall on that day. The numbers so tabulated have from the later middle ages been known as *Golden Numbers*. The same tables placed against each day its Sunday Letter. So that to find the date of Easter all that was required was to see against which day the Golden Number of the year stood and then to see which was the next day against which the Sunday Letter of the year stood; the day so found would be Easter day. This method is retained in the English Prayer Book, but the positions of the Golden Numbers have to be changed in the centurial years whenever the date of the Easter full moon corresponding to a given year of the 19-year cycle is changed.

In the tables issued by authority of Pope Gregory XIII, Easter is found by means of *Epacts* instead of by Golden Numbers. The Epact is the age of the moon on some fixed day of the calendar year. In the Alexandrian Easter tables the age

on the first day of the Alexandrian calendar (August 29-30) was shown. Dionysius Exiguus and Bede, writing for a western public, preferred to describe this as the moon's age on March 22. Tables adapted to the Roman cycle of 84 years showed the moon's age on the first day of the Roman year, January 1. So also do the tables adapted to the Gregorian calendar. If the moon's age on the first day of the year is known, then by counting months of 30 days and 29 days alternately, the approximate age of the moon is known for every day of the year. The epacts in the Easter calendars vary in the same manner as the Golden Numbers. The English Prayer Book shows the epact, but makes no use of it.

*Movable Festivals.*—In the ecclesiastical calendar some holy days are observed on fixed days of the year. Others, known as movable festivals, are observed on fixed days of the week. Most of these are at fixed intervals before or after Easter Day. The following holy days dependent on the date of Easter are shown in the *Nautical Almanac*.

Days before Easter			Days after Easter		
Septuagesima Sunday	...	63	Low Sunday	...	7
Quinquagesima Sunday	...	49	Rogation Sunday	...	35
Ash Wednesday	...	46	Ascension Day	...	39
Quadragesima Sunday	...	42	Whit Sunday	...	49
Palm Sunday	...	7	Trinity Sunday	...	56
Good Friday	...	2	Corpus Christi	...	60

The First Sunday in Advent is the fourth Sunday before Christmas Day, and is therefore the nearest Sunday to November 30.

*Julian Period.*—The French Protestant scholar and chronologist Josephus Justus Scaliger invented the Julian Period as a practically continuous measure of time. It combines the Solar Cycle of 28 years, the Lunar Cycle of 19 years and the Cycle of the Indiction comprising 15 years, thus containing  $28 \times 19 \times 15 = 7980$  years altogether. All these cycles are supposed to begin on January 1 of the Julian calendar, and it is found that they began together in 4713 B.C., so that one Julian Period includes all dates both in the past and in the future to which reference is likely to be made, and to that extent has an advantage over an era whose epoch lies within the limits of historical time.

The years of the Julian period are seldom employed now, but the day of the Julian period is frequently used in astronomy and in calendrical tables. It is the only method of enumerating days that is free from their combination into months and years, and is therefore particularly useful where an exact interval in days is required. The Julian days are numbered consecutively from Greenwich mean noon on January 1 4713 B.C., at which date the Julian Day was 0.0.

*Mohammedan Calendar.*—The Mohammedans use the Era of the Hegira beginning with the year of Mohammed's flight or Hegira in A.D. 622. The peculiarity of the Mohammedan calendar is that each year consists of 12 lunar months without intercalation, so that each month goes the round of the seasons in 33 years. For religious purposes the beginning of each month is fixed by observation of the lunar crescent. For the purposes of civil life there has never been an exact rule, and different beginnings of the month have been used by different people living in the same town. It is, therefore, impossible to give an exact interpretation to a date expressed in this calendar unless the day of the week is given as well as the day of the month; this applies both to public and to private documents. For astronomical purposes a more exact rule is followed; the months have 30 days

and 29 days alternately, except the 12th month, which has 29 days nineteen times and 30 days eleven times in a cycle of 30 Mohammedan years. In consequence the calendar makes 360 lunations equal to 10631 days; their real duration is 10631.012 days. The error, therefore, amounts to no more than a day in 2500 years. There are two forms of this cycle; they give dates differing by one day in 348 of the 360 months of the cycle.

*Subdivisions of the Day.*—From a remote antiquity the Egyptians divided each day and each night into twelve equal hours. These necessarily varied in length with the season of the year and were in consequence termed *ὥραι καιρικαί* in Greek and *horæ temporales* in Latin. The same method of dividing the day and night was used along with other methods in Babylonia and Assyria, where each day and each night was divided into three watches, each of four temporal hours.

In astronomical observations and predictions the Babylonians expressed time in *bēru*, *geš* and *G.A.R.* The whole interval of day and night combined was divided into twelve *bēru* of uniform length, each *bēru* into thirty *geš* and each *geš* into sixty *G.A.R.* The division of the day into *bēru* and *geš* was probably on the analogy of the division of the year into twelve months of thirty days each. From being measures of time these terms appear to have become measures of hour angle and finally measures of arc and of angles generally. The *geš*, which was the 360th part of the day, survives in our degree. The sexagesimal subdivision of the *geš* is in accordance with the Sumerian system of arithmetical notation, inherited by the Babylonians\*, which was similar to our own decimal system of expressing both integers and fractions except that it was sexagesimal throughout instead of decimal. These intervals of time were measured to or from sunrise or sunset.

In Kidinnu's tables the *bēru* is not used, but the interval from midnight to midnight is divided into six mean watches. The *geš* as the sixtieth part of the mean watch, and the *G.A.R.* as the sixtieth part of the *geš* form the next subdivisions, and the *G.A.R.* in its turn is divided into sixty parts, so that the whole subdivision of the mean watch is strictly sexagesimal. While for civil and religious purposes and for astronomical observations and predictions the day was reckoned from sunset, Kidinnu reckoned it from midnight, which is obviously a more convenient starting point for astronomical tables.

The division of day and night into temporal hours spread through the Græco-Roman world during the Hellenistic period. These were always numbered from sunrise and sunset, although the official beginning of the day varied from one country to another. Thus at Athens and in western Asia the day began officially at sunset, and at Rome at midnight, while in Egypt the night was generally regarded as lying between two days, and the numbers of both days are given to express the time at night. Sun-dials were devised to shew the temporal hours and Ptolemy introduced lines on the astrolabe for this purpose.

For astronomical purposes the equinoctial hour, i.e. the mean temporal hour or the temporal hour with the length that it had at the equinoxes, was introduced; it is found first in Hipparchus. According to Pliny, he, like the Babylonians, reckoned the day from midnight. Ptolemy in the tables in the *Almagest* reckoned the day from mean noon of Alexandria and divided the whole day into sixty equal parts, each of which was divided sexagesimally, as far as was necessary. But it appears that in his *Manual Tables*, he divided the whole day into equinoctial hours reckoned from mean noon of Alexandria, and subdivided these sexagesimally, thus having our system of 24 equal hours to the day, with a subdivision into minutes and

\* See F. Thureau-Dangin, *Esquisse d'une histoire du système sexagésimal* (1932), especially chapter V.

seconds. Apart from the selection of mean noon as the initial point this was probably the same system as that of Hipparchus. The 24-hour system reckoned from mean noon established itself in astronomical tables and ephemerides generally within the limits of Greek, Latin and Arabic civilisation, and, subject only to changes in the adopted meridian, remained in use till 1925.

The use of temporal hours for the ordinary purposes of life was not disturbed till the invention in the fourteenth century of mechanical clocks, striking the hours. It was well nigh impossible to make clocks strike hours of unequal length, and in consequence these clocks struck the equinoctial hours from the first. In Italy and Bohemia clocks were set to number and strike the hours from dusk or about half an hour after sunset and the hours were numbered up to twenty-four, though, so far as striking was concerned, the twenty-four hours were in some clocks divided into two series of twelve, the second series beginning twelve equinoctial hours after dusk. In most other countries the clocks both numbered and struck the hours in two series of twelve hours beginning at midnight and noon respectively. In England, where these hours were used extensively before the end of the fourteenth century, hours so reckoned were described as "of the clock" or "o'clock", to distinguish them from the older reckoning of hours of the day and night. The two series of twelve hours were from the first commonly distinguished as "before noon" (*ante meridiem*) and "after noon" (*post meridiem*). The introduction of the equinoctial hour into civil life was accompanied by the introduction of its astronomical subdivisions, the minute and the second. Sun-dials constructed to show equinoctial time measured from midnight and noon have been constructed since the fifteenth century.

The Italian method of reckoning time up to 24 hours from dusk was abandoned in the early part of the nineteenth century, except in Turkey where time was still reckoned in two series of equinoctial hours beginning at sunset and twelve hours after sunset respectively.

The time used for civil purposes from the introduction of clocks till the close of the eighteenth century was local solar time. The substitution of mean time took place in most countries late in the eighteenth or early in the nineteenth century, at London in 1792.

The development of railways led to the adoption of a single meridian for each country or each railway administration, Greenwich time being made the legal time in Great Britain in 1848. Afterwards the time referred to local meridians gave place in most countries to zone time, differing from Greenwich time by a whole number of hours (or occasionally half-hours), adopted in Sweden in 1879, on most of the American railways in 1883, and in most European countries before the end of the nineteenth century.

Since 1916 various countries or places have for part of the year adopted for civil purposes a reckoning of time known as "summer time", one hour in advance of the time reckoned from the adopted mean noon or mean midnight. As this reckoning is governed only by practical convenience, there has been no uniformity in the action of the authorities that have adopted it.

From the beginning of 1925 the principal ephemerides have reckoned the day and numbered the hours from mean midnight to mean midnight instead of from mean noon to mean noon. The same system, adapted when necessary to zone time and summer time, has since the last years of the nineteenth century been used in various places for various non-astronomical purposes, mostly of an official or semi-official character.

## TIME

The astronomical clock, by means of which time is measured, is the Earth, whose axial rotation causes the heavenly bodies to appear to revolve round the Earth from east to west. For the hands of this clock the Sun, Moon or stars may be selected, and different times will result according to the choice made. The most convenient unit of measure for time is the day, which is defined as the interval between successive transits (over the same meridian) of the heavenly body by which the time is measured. If the heavenly bodies were absolutely fixed, all days would be of the same length, this length corresponding exactly to the Earth's period of rotation. But the movements of the various heavenly bodies or other reference points are different and non-uniform, and consequently days of different and varying length arise.

The **apparent solar day** was formerly considered to begin and end at **apparent noon**, the moment when the centre of the true Sun is on the upper meridian, but since 1925 January 1 it has been considered to begin and end at apparent midnight, the moment of lower meridian passage of the true Sun. It is divided into 24 hours, and the time resulting is called **apparent time**. Thus apparent time at any instant is the westward hour angle of the true Sun  $+ 12^h$ .

Owing to the non-uniform motion of the true Sun in right ascension, arising partly from the fact that it moves in the ecliptic and not in the equator, and partly from the eccentricity of the Earth's orbit, the apparent solar day is of variable length, and is therefore not suitable as a measure of time, because the clocks made by man to record time are, of necessity, designed to move uniformly. Hence a fictitious mean sun is conceived which moves *uniformly*\* in the equator with the same mean motion as that of the true Sun. The interval between successive transits of this mean sun constitutes the **mean solar day**, which is the common day of civil life, and gives rise to **mean solar time**, or more simply **mean time**.

As the mean sun crosses the meridians on the earth at different moments, there arise numerous **local mean times**, each defined by the passage of the mean sun across a particular meridian. To avoid the confusion that would ensue if these were all in use, it is convenient to regard the time of some one meridian as a standard. By common consent the meridian of Greenwich is universally accepted as the prime meridian, and **Greenwich Mean Time**, usually abbreviated G.M.T., is the standard to which all other mean times are referred. Since the Earth rotates uniformly on its axis, and since longitudes are measured uniformly round the Earth from the meridian of Greenwich, it follows that the difference between Greenwich mean time and the local mean time of any place is equal to the longitude of that place. Denoting by  $\lambda$  the longitude, considered positive to the west, we have, since the Earth rotates from west to east,

$$\text{Local mean time} = \text{G.M.T.} - \lambda$$

In actual practice it would be extremely inconvenient if local mean times were adopted by each community, so the time over a large area is reckoned from some one convenient meridian, and called the **Standard Time** for that area or country. Usually the standard time differs from Greenwich mean time by an integral number of hours. A list of the standard times adopted by the principal countries of the world is given on pages 704-713. In some countries the legal time during the summer months is in advance of the standard time, and is then usually designated **Summer**

---

\* See also page 785.

**Time.** This time is, however, never used in astronomical ephemerides, or in the recording of astronomical observations.

In the case of a vessel at sea the term **Ship Mean Time** is frequently used instead of **Local Mean Time**. This must not be confused with **Ship Time**, which is the time shown by the ship's clocks. In the merchant and passenger services it is customary to alter the clocks each night by an integral number of minutes so that at local noon on the following day the ship time shall be approximately 12<sup>h</sup>. In the British Navy **Zone Times**, differing by integral hours from Greenwich mean time, are used. Each zone extends for 7°·5 or 30<sup>m</sup> on both sides of the meridian from which it takes its name. Thus all vessels between longitudes 22°·5 and 37°·5 west would use the zone time +2<sup>h</sup>, i.e. G.M.T. - 2<sup>h</sup>.

Before 1925 January 1 the astronomical day was considered to begin at mean noon, or at the moment of upper meridian passage of the mean sun, and astronomical clocks indicated 0<sup>h</sup> at that moment and 12<sup>h</sup> at mean midnight. Greenwich mean time was then usually defined as the Greenwich westward hour angle of the mean sun. Since that date, however, the day has been considered to begin at mean midnight, or the time of lower meridian passage of the mean sun, and the definition of Greenwich mean time has been changed so that it is now the Greenwich hour angle of the mean sun + 12<sup>h</sup>. Thus the astronomical day 1924 December 31 was only 12 hours long and 1924 December 31·5 old time reckoning is the same as 1925 January 1·0 new time reckoning. Since, as far as the *Nautical Almanac* is concerned, no change of name has been made, but merely a change of definition, it is highly important that in expressing all times prior to 1925 January 1 the old definition should be the only one permitted, while in the case of times since that date the new definition should be followed rigorously. It has been felt by some astronomers that a new name should be given to the time commencing at midnight, and in the *American Ephemeris* and the *Connaissance des Temps* the term **Greenwich Civil Time** (G.C.T.) is used, in the *Berliner Jahrbuch Weltzeit* (World Time), while a number of astronomers have adopted **Universal Time** (U.T.). For cases where it is desired to express a time after 1925 January 1 by the former method of reckoning, the term **Greenwich Mean Astronomical Time** (G.M.A.T.) is now reserved.

The difference between mean time and apparent time is known as the **equation of time**. This quantity is also the difference between the hour angles of the mean and true suns, or between their right ascensions. When this term was first introduced it was the practice to determine apparent time from a sun-dial, or from observations of the Sun, so that the equation of time was then considered to be mean *minus* apparent time, or the correction to be applied to apparent time to reduce it to mean time. To-day mean time is ascertained by the astronomer by conversion of the sidereal time obtained from stellar observations, and by the navigator from wireless signals, so that the *Nautical Almanac* now tabulates the correction to be applied to mean time to give apparent time.

The interval between two successive passages over the meridian of any place of an equatorial star without proper motion constitutes the **sidereal day**, properly so-called. This interval is 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>·100 of mean solar time, and equals, of course, the period of the Earth's axial rotation. But in actual practice transits, not of a star, but of the position of the vernal equinox or first point of Aries, are used to define the sidereal day. Since the equinox has an annual retrograde motion along the ecliptic of about 50", due to precession, the adopted sidereal day is 0<sup>s</sup>·009 shorter than the period of rotation, and is, therefore, 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>·091, measured in mean solar

time. From this figure the mean solar day is easily deduced to be  $24^{\text{h}} 03^{\text{m}} 56^{\text{s}}.555$  of sidereal time. A sidereal clock, showing **sidereal time**, will indicate  $0^{\text{h}}$  at the moment of passage of the vernal equinox, and will divide the sidereal day into 24 sidereal hours.

The **right ascension** of a body may be defined as the interval, measured in sidereal time, between the transit of the vernal equinox and the transit of the body. In other words, when the body is on the meridian the sidereal time is equal to its right ascension. Applying this principle to the mean sun it follows that the sidereal time at the moment of meridian passage of the mean sun, which, by definition, is mean noon, is equal to the right ascension of the mean sun. Thus it is essentially a knowledge of the right ascension of the mean sun that permits the conversion of mean time into sidereal time or vice versa. At mean midnight the sidereal time is obviously  $12^{\text{h}}$  greater than the right ascension of the mean sun, and in the *Nautical Almanac* this right ascension, increased by  $12^{\text{h}}$ , is given for every midnight or  $0^{\text{h}}$  under the heading "Sidereal Time". The sidereal time at any moment may be found by adding the equivalent in sidereal time (taken from Table III) of the mean time to the sidereal time at  $0^{\text{h}}$ . The inverse problem may be solved by subtracting the sidereal time at  $0^{\text{h}}$  from the given sidereal time, and converting the remainder into mean time by Table IV.

An alternative method of conversion is afforded by the tabulation of the mean time of **transit of the first point of Aries**, which is computed by converting the complement to  $24^{\text{h}}$  of the sidereal time at  $0^{\text{h}}$  into its equivalent interval of mean time. The conversion of mean to sidereal time may be effected by subtracting the time of previous transit from the given mean time, and converting the remainder into its equivalent interval of sidereal time (Table III). A given sidereal time may be converted into an equivalent interval of mean time (Table IV) and added to the *preceding* transit of the first point of Aries to yield the corresponding mean solar time.

A complication is introduced by the fact that the precession of the equinoxes is not uniform, but is affected by irregularities known as **nutation**, due to solar and lunar perturbations. The **mean equinox** of date is conceived to be a point moving uniformly (except for a slight secular acceleration) along the equator, while the difference in right ascension between this point and the true equinox (in the sense true — mean) is called **nutation in right ascension**. This may amount to about  $\pm 1^{\text{s}}.2$ . The right ascension of the mean sun is measured from the true equinox, and hence does not increase uniformly, nor are the sidereal days, measured by transits of the true equinox, of equal length. This is illustrated by a table showing the sidereal time at  $0^{\text{h}}$  at intervals of 90 days.

Date	Sidereal Time at $0^{\text{h}}$
1935 Jan. 1	$6^{\text{h}} 38^{\text{m}} 52^{\text{s}}.185$
Apr. 1	$12^{\text{h}} 33^{\text{m}} 42^{\text{s}}.196$
June 30	$18^{\text{h}} 28^{\text{m}} 32^{\text{s}}.249$
Sept. 28	$0^{\text{h}} 23^{\text{m}} 22^{\text{s}}.217$
Dec. 27	$6^{\text{h}} 18^{\text{m}} 12^{\text{s}}.267$

The nutation is, for convenience, usually divided into two parts. One part, depending on the longitude of the Moon's node, the Sun's longitude and the longitude of the Sun's perigee, constitutes the long-period terms, while the other, involving functions of the Moon's longitude, constitutes the short-period terms. The long-period terms have a principal period of 18 years and vary between  $\pm 1^s.2$ ; the principal short-period term has a period of half a lunar month, or nearly 15 days, while the combined effect of the short-period terms may attain  $\pm 0^s.020$ .

The introduction of clocks led to the necessity for mean solar time; the accurate time-keeping of modern clocks is leading to the use of a mean or **uniform sidereal time**, related to true sidereal time as determined by transit circle observations of stars by the equation

$$\text{Uniform sidereal time} = \text{true sidereal time} - \text{nutation}.$$

The following table shows the analogy between solar and sidereal times:—

	Solar	Sidereal
Observations determine ...	Apparent solar time ...	True sidereal time
Clocks keep ...	Mean solar time ...	Uniform sidereal time
The difference is ...	Equation of time ...	Nutation in R.A.

To facilitate the use of uniform sidereal time, the sidereal time and the nutation in right ascension are tabulated to three decimals, and include the short-period terms. The mean time corresponding to a given uniform sidereal time is the mean time equivalent of (given uniform sidereal time — true sidereal time at 0<sup>h</sup> + nutation at 0<sup>h</sup>).

All ephemerides are computed on the assumption that time moves uniformly, and that the length of a day, whether mean solar or uniform sidereal, is invariable, except for a small recognised secular variation. It is now believed that the rotation of the Earth, upon which the length of the day depends, is not constant. Such a change, although imperceptible from day to day, would lead to a cumulative error in time reckoning, so that the observed time as shown by a clock might differ by many seconds from the time that the compilers of the tables of the Sun, Moon and planets expected the clock to show at a given moment, the effect of this error being revealed, not as an apparent clock error, but as an apparent error in the ephemerides of the Sun, Moon and planets. It was the correlation of these apparent errors that led to the announcement of the variability of the Earth's period of rotation.

The ephemerides in the *Nautical Almanac* are all based strictly on the tables mentioned, and, except in the case of eclipses and occultations, no attempt is made to correct the positions derived from the tables in order to bring them into accord with modern observations. There are two reasons for this policy; firstly because subsequent comparison of observations with theory is rendered less certain if arbitrary and changing corrections are applied to the theoretical positions, and secondly because the ephemerides of the Sun, Moon and planets may be prepared for as much as ten years in advance of final publication. For refined work, such as the determination of the definitive orbit of a comet or minor planet, or the preparation of an accurate ephemeris of such a body, it may be deemed advisable to apply corrections based on recent observations. This is most conveniently done, in the case of the Sun and Moon, by adopting a value of the correction ( $\Delta\lambda$ , in seconds of

arc) to the mean longitude, and then entering the ephemeris at a time differing from the given G.M.T. by the time required by the body to move through  $\Delta\lambda$  seconds of mean longitude. Since, at present, both  $\Delta\lambda_0$  and  $\Delta\lambda_1$  are positive, the correction required by a G.M.T. before entering the ephemeris is

$$\begin{aligned} &+0^d.000282 \Delta\lambda_0 \text{ for the Sun} \\ &+0^h.000506 \Delta\lambda_1 \text{ for the Moon.} \end{aligned}$$

For the year 1935,  $\Delta\lambda_0$  and  $\Delta\lambda_1$  may be expected to be approximately  $+1''.6$  and  $+5''$  respectively.

## EQUINOXES

The **vernal equinox**, or **first point of Aries**, is defined as that intersection of the equator and ecliptic through which the Sun passes when crossing the equator from south to north. On account of the movements of the equator and ecliptic the equinox is continually shifting. Its movement may be resolved into two portions, one of which, known as **precession**, causes the equinox to retrograde along the ecliptic or equator at a nearly uniform rate, while the other, known as **nutation**, causes a periodic displacement of the equinox from the position that it would have if affected by precession alone. When the effect of nutation is removed the resulting fictitious equinox is called the **mean equinox**. Its instantaneous position at any moment of time is the **mean equinox of date**, while its position at the beginning of the Besselian fictitious year is known as the **mean equinox of the beginning of the year**, or, more briefly, for the year 1935, the **equinox of 1935.0**. The intersection of the true equator and ecliptic is the **true or apparent equinox**.

The Besselian fictitious year, sometimes known as the solar year, is used in astronomy because of the incommensurability of the calendar and tropical years. Its length is the tropical year of  $365^d.24219879 - 0^d.00000614T$ , where  $T$  is measured in centuries from 1900, and the beginning, which is always near the beginning of the calendar year, is defined as the moment when the right ascension of the mean sun, affected by aberration and measured from the mean equinox, is  $18^h 40^m$ . A definition that is equivalent (except for a small term in  $T^2$ , as is explained on page 785) is that it is the moment when the Sun's mean longitude, affected by aberration, is  $280^\circ$ . The mean longitude tabulated on page 54 and defined on page 784 is freed from aberration; since Newcomb used  $20''.50$  as the constant of aberration, we may conveniently determine the beginning of the Besselian fictitious year as the moment when the Sun's mean longitude, freed from aberration, is  $280^\circ.0057$ . The notation 1900.0, which is used to denote the beginning of the Besselian fictitious year 1900, should never be used to denote an epoch like 1900 January 0, Greenwich mean noon.

Since nutation arises from the action of the Sun and Moon on the Earth, it does not affect the position of the ecliptic, but only that of the equator, and consequently nutation does not affect the latitudes of heavenly bodies. The ecliptic is, however, not fixed in space, but changes its position slowly on account of the action of the other planets on the Earth's orbit. Since the ecliptic is the fundamental plane to which other planes in the solar system are referred, the ecliptic of any one date must be referred to the position of the mean ecliptic of some specified date. The ascending node of the ecliptic of the instant  $t + dt$  on the ecliptic of the instant

$t$  is the quantity denoted in these pages by  $\Pi$  (approximately  $174^\circ$ ), while the annual change in the inclination of the moving ecliptic to its fixed position at some instant is  $\pi$  (approximately  $0''.471$ ). The term true ecliptic, which would denote the instantaneous orbit of the Earth round the Sun, is not used.

The inclination of the ecliptic to the equator, known as the **obliquity** of the ecliptic, varies on account of the combined movements of these two planes, and, as we have just seen, the movement of the equator is affected by nutation, so that we introduce the idea of a mean equator, and hence of a mean obliquity, a mean obliquity of date, a mean obliquity for the beginning of the year, and a true or apparent obliquity, as in the case of the equinox. The difference true obliquity minus mean obliquity of date is the **nutation in obliquity**. The **nutation in longitude** is the arc of the ecliptic intercepted between the mean and the true equators, and is given in the sense in which such quantities are usually given in astronomy, i.e. as the correction to be added to a mean longitude to give apparent longitude. The **nutation in right ascension** will be equal to the nutation in longitude multiplied by the cosine of the obliquity, and reduced to time. The apparent obliquity and the nutation in obliquity are no longer tabulated directly in the *Nautical Almanac*, but may be readily obtained as follows:—

Mean obliquity for beginning of the year, see page 54

Reduction to mean obliquity of date =  $-0''.468 \tau$

Nutation in obliquity, long-period terms =  $-B$  (pages 266-273)

Nutation in obliquity, short-period terms =  $-B'$  (pages 266-273)

It has been the practice to refer the solar, lunar, planetary and stellar ephemerides to the apparent equinox, so that they may be compared directly with observations. But in theoretical work, and in the intercomparison of observations, it is generally necessary to employ some fixed equinox. In this connection use is made of the mean equinox of the beginning of the year in such work as the determination of cometary orbits, and as an intermediate stage in the reduction of observations of stars to a form in which they can be combined. In the computation of perturbations of comets and minor planets, and in the combination of observations of star positions into a single catalogue, it is necessary to go a stage further, and to adopt a few widely separated equinoxes. The equinox of 1950.0 has been suggested\* as a standard equinox for the next fifty years or so. The Sun's longitude, latitude and equatorial rectangular co-ordinates are now given in each *Almanac* for that equinox. In the case of the planets, instead of publishing year by year the co-ordinates for the equinox of 1950.0, they will be issued in separate volumes, each covering twenty years. The volume† for the years 1920-1939 was published in 1933, and is described on page-777. It is anticipated that the volume for 1940-1960 will be published in 1939.

The ephemerides of minor planets, published by the Astronomisches Rechen-Institut of Berlin, are now for the equinox of 1925.0, but will shortly be changed to that of 1950.0. The steps taken by the national ephemerides to facilitate the adoption of the equinox of 1950.0 as a standard formed the subject of a special

\* L. J. Comrie, "The Use of a Standard Equinox in Astronomy." *M.N.R.A.S.*, 86, 618 (1926 June).

† *Planetary Co-ordinates for the years 1800-1940, referred to the Equinox of 1950.0*. London, H. M. Stationery Office, 1933. 12s. 6d. net.

resolution of approval at the meeting of the International Astronomical Union at Leiden in 1928 July.

The position of a star, when referred to a specified mean equinox, is spoken of as the **mean position** for that equinox. In some cases the position is said to be for a certain equinox, but for a different **epoch**; this means that, when reducing to the specified equinox the position observed at the epoch, no correction for proper motion has been applied. Or, on the other hand, the position may have been taken from a catalogue, and a correction for proper motion deliberately applied so that the position of the star, in so far as proper motion is concerned, is that appropriate to the epoch, whereas the axes of reference are those of the equinox specified. In mean positions of stars the effect of stellar aberration has always been removed.

The **apparent position** of a heavenly body is the position in which it would be seen by an observer, i.e. it has been corrected for precession and nutation, so that it is referred to the true equator and equinox of date; it has been corrected for stellar aberration, or, in the case of a body in the solar system, for planetary aberration; also it has been corrected for proper motion and, if necessary, for parallax. In the *Nautical Almanac* the apparent positions of stars are corrected for annual parallax where this is known and is sensible. The ephemerides of the members of the solar system are geocentric, so that no correction for horizontal parallax requires to be included.

### STANDARD EQUINOX OF 1950.0

The volume\* *Planetary Co-ordinates for the Years 1800-1940, referred to the Equinox of 1950.0*, together with quantities now given in the *Nautical Almanac*, enable this equinox to be used for all purposes for which a fixed equinox is desirable. The volume contains values of the heliocentric longitude, latitude, radius vector and equatorial rectangular co-ordinates, and of the equatorial rectangular components of the attraction of the planet on the Sun. For the years 1920-1939, Venus, Mars and Jupiter are given at intervals of 10 days, Saturn at 20, Uranus and Neptune at 40. For the years 1900-1920 Jupiter and Saturn are given at intervals of 40 days, while for 1903-1920 Uranus and Neptune are given at intervals of 160 days. For 1800-1900 heliocentric spherical co-ordinates of Jupiter and Saturn are given at intervals of 100 days. The volume also gives tables of the mean obliquity and its trigonometrical functions, ecliptic and equatorial precessional elements, tables for reduction of equatorial rectangular co-ordinates from any equinox to 1950.0 or vice versa, tables for reduction of star positions from the equinoxes of 1875.0, 1900.0 and 1925.0 to that of 1950.0 and vice versa,  $\frac{1}{r^3}$  with argument  $r^2$ , Encke's  $f_4$  table in natural form, masses, and collected formulæ. The calculation of the special perturbations of a comet or of a minor planet by Encke's and by Cowell's method is described and illustrated.

The *Nautical Almanac* itself provides

- (1) Sun's co-ordinates, both spherical and rectangular, for the equinox of 1950.0. (Pages 38-53).
- (2) Precessional constants. (Page 54).

---

\* London, H. M. Stationery Office, 1933. 12s. 6d. net.

- (3) Quantities for the application of differential precession, nutation and aberration. (Pages 275-295).
- (4) Tables for the rigorous reduction of star positions from the equinox of the beginning of the year to that of 1950.0. (Tables XIII and XIV).
- (5) Tables for reducing a finding ephemeris from the standard equinox of 1950.0 to the true equinox of date. (Table XV).

### LONG-PERIOD AND SHORT-PERIOD TERMS

It has been the practice to divide the terms of nutation into long-period terms, which do not depend on the Moon's longitude, and short-period terms, which do. The reasons for this were firstly, that the short-period terms are small, being usually negligible in comparison with the probable error of a single observation, so that no systematic error is caused by their neglect. Secondly, the apparent places of stars are usually given at intervals of ten days, and the short-period terms cannot be interpolated at such wide intervals; consequently they are omitted, but means are provided for their inclusion when desired. The increased accuracy now attainable in meridian circle observations is resulting in the more frequent inclusion of these terms, especially in accurate time-keeping and longitude determination. No theoretical reason exists for the separation or exclusion of short-period terms; the treatment adopted has been solely a matter of convenience.

In the ephemerides of the Sun, Moon and planets short-period terms are omitted, and it is contemplated that this practice will continue for some years at least; as already remarked no systematic error is thereby introduced into the comparison of observation with theory. In any case the further corrections necessary could readily be computed from the functions tabulated on pages 275-289 by the formulæ

$$\begin{aligned}\Delta\alpha &= f' + \frac{1}{18}g' \sin(G' + \alpha) \tan \delta \\ \Delta\delta &= g' \cos(G' + \alpha)\end{aligned}$$

The corrections to the apparent places of the stars on pages 358-520 are more conveniently expressed in the form

$$\begin{aligned}\Delta\alpha &= A'a + B'b \\ \Delta\delta &= A'a' + B'b'\end{aligned}$$

$A'$  and  $B'$  being given on pages 266-273, and  $a$ ,  $a'$ ,  $b$  and  $b'$  being tabulated for each star.

It must be noted that these terms are already included in the ephemerides of circumpolar stars on pages 308-357.

### UNIT OF DISTANCE

The unit of distance in the solar system is the mean distance of the Earth from the Sun. Using Hayford's value of 3963.34 miles for the Earth's equatorial radius, and the adopted value of  $8''.80$  for the Sun's equatorial horizontal parallax, this distance is 92,900,000 miles or 149,500,000 kilometres, the logarithms of which may be taken as 7.9680 and 8.1746 respectively.

## THE NAUTICAL ALMANAC

In the *Nautical Almanac* for 1931, under the heading DERIVATION (pages 802-827), the calculation of many of the quantities tabulated was illustrated in full.

The lists of mathematical tables given in the *British Astronomical Association Handbook* for 1929, and in the *Monthly Notices of the Royal Astronomical Society*, 92, 338 (1932 February), include most of the tables used in compiling the *Almanac*. The calculating machines in use are Burroughs, Hollerith, Mercedes, Monroe, National (Ellis) and Nova-Brunsviga. Descriptions of these machines, and of the work done with them, will be found in

- (1) "On the Application of the Brunsviga-Dupla Calculating Machine to Double Summation with Finite Differences." *M.N.R.A.S.*, 88, 447. (1928 March).
- (2) "On the Construction of Tables by Interpolation." *M.N.R.A.S.*, 88, 506. (1928 April).
- (3) "Recent Developments in Calculating Machines." *Office Machinery Users' Association Transactions*, 1927-28.
- (4) "Modern Babbage Machines." *Office Machinery Users' Association Transactions*, 1931-32.
- (5) "The Nautical Almanac Office Burroughs Machine." *M.N.R.A.S.*, 92, 523. (1932 April).
- (6) "The Application of the Hollerith Tabulating Machine to Brown's Tables of the Moon." *M.N.R.A.S.*, 92, 694. (1932 May).
- (7) "Computing the Nautical Almanac." *Nautical Magazine*, 1933 July.
- (8) "The Hollerith and Powers Tabulating Machines." Privately printed, 1933.

It is to be noted that in all cases, unless otherwise stated, or unless inconsistent with the headings of the page (e.g. Ephemerides at Transit at Greenwich) the quantities given are for  $0^h$  G.M.T. on the dates concerned.

*Calendar* (Pages 1-5)

The special article on the calendar (page 754) and the explanation at the foot of page 2 may be consulted.

*Sun* (Pages 6-21)

The *Apparent Right Ascension* and *Apparent Declination* are referred to the true equinox of date and are affected by aberration and the long-period terms of nutation; they therefore represent the apparent position of the true Sun. They are computed from the Sun's longitude and latitude by the formulæ

$$\begin{aligned}\cos \delta_0 \cos \alpha_0 &= \cos \lambda \\ \cos \delta_0 \sin \alpha_0 &= \sin \lambda \cos \epsilon - 19.3 \beta \\ \sin \delta_0 &= \sin \lambda \sin \epsilon + 44.5 \beta\end{aligned}$$

where  $\lambda$  includes nutation, but not aberration,  $\beta$  is in seconds of arc and the numerical coefficients in units of the seventh decimal. The aberration, or correction to the Sun's position to allow for its motion during the time taken by light from the

Sun to reach the Earth, is based on the assumption that light travels unit distance in  $498^{\text{s}}.38$  (corresponding to a constant of aberration of  $20''.47$ ) and is, therefore,

$$\begin{aligned}
 & - \frac{498.38 R \times \text{motion in } 2^{\text{d}}}{60 \times 60 \times 24 \times 2} \\
 & = -0.0028841 R \times \text{motion in } 2^{\text{d}}
 \end{aligned}$$

The motion in  $2^{\text{d}}$  is obtained by subtracting  $\alpha_0$  (or  $\delta_0$ ) on the day before that for which the calculation is being made from the value on the day following. Theoretically the aberration could have been applied to  $\lambda$ , but it is excluded as the quantities on the right-hand side of the above equation are required when determining values of the Sun's rectangular equatorial co-ordinates  $X, Y, Z$  to be used in converting heliocentric positions of the planets to geocentric positions (see page 793). The quantities  $\sin \lambda$  and  $\cos \lambda$  are also required in forming the Besselian day numbers  $C$  and  $D$  (see page 795).

The *Semi-diameter* at unit distance is taken as  $16' 01''.18$ . A smaller value (see page 801) is used in the computation of eclipses. The tabulated value is the value at unit distance divided by the Sun's radius vector.

The *Equation of Time*, tabulated in the sense apparent *minus* mean, is the correction to be added to mean time to give apparent time. It is found from

$$\text{Sidereal Time at } 0^{\text{h}} \pm 12^{\text{h}} - \text{Sun's apparent R.A.}$$

The *Sidereal Time* is, at midnight,  $12^{\text{h}} +$  the right ascension of the mean sun, affected by aberration, + nutation in right ascension. The short-period terms of nutation, whose combined effect may attain  $\pm 0^{\text{s}}.020$ , are included. Their effect may be removed by subtracting  $f'$ . See *uniform sidereal time* (page 774), *nutation in right ascension* (page 781), Table III (page 718) and explanation of Table III (page 849).

The use of the sidereal time at  $0^{\text{h}}$  in converting a given mean time into sidereal time is illustrated in Table III, page 718. The right ascension of the mean sun, affected by aberration, is, according to Newcomb

$$18^{\text{h}} 38^{\text{m}} 45^{\text{s}}.836 + 8640184^{\text{s}}.542 T + 0^{\text{s}}.0929 T^2$$

where  $T$  is measured in Julian centuries of 36525 days from 1900 January  $0^{\text{d}} 0^{\text{h}}$  (J.D. 2415020.0).

The *Sun's Longitude and Latitude*, which are taken from Newcomb's *Tables of the Sun*, are referred to the mean equinox of the beginning of the year. The apparent longitude is equal to the longitude referred to the mean equinox of the beginning of the year + precession in longitude + nutation in longitude - aberration. The apparent latitude is equal to the mean latitude -  $0''.471 \tau \sin(\lambda - \Pi)$ ,  $\tau$  being given on pages 275-289, and  $\Pi$  on page 54.

The *Radius Vector of the Earth* is the distance from the centre of the Sun to the centre of the Earth, measured in astronomical units. It is taken from Newcomb's *Tables*, and is independent of the equinox. Natural values are given on pages 38-45.

The *Precession in Longitude* is the precession since the beginning of the Besselian fictitious year for a point on the ecliptic, and is equal to  $p\tau$ . For other points the further correction  $+0''.471 \tau \cos(\lambda - \Pi) \tan \beta$  must be applied.

The *Nutation in Longitude*, which does not include short-period terms, is the correction to be added to a longitude referred to the mean equinox of date to give the longitude referred to the true equinox of date, which, when aberration has been

subtracted, becomes the apparent longitude. It is independent of the latitude. The short-period terms are  $+50''\cdot37 A'$ . The terms included are

$$\begin{aligned} & -(17\cdot234 + 0\cdot017 T) \sin \Omega \\ & + 0\cdot209 \sin 2\Omega \\ & - 1\cdot272 \sin 2L \\ & + 0\cdot126 \sin(L - \Gamma) \\ & - 0\cdot050 \sin(3L - \Gamma) \\ & + 0\cdot021 \sin(L + \Gamma) \\ & + 0\cdot012 \sin(2L - \Omega) \end{aligned}$$

The *Nutation in Right Ascension*, which includes short-period terms, is tabulated for use in connection with accurate time-keeping, as explained in the article on time (page 771). It is the correction to be added to the right ascension of a body in the equator (e.g. the mean sun) to reduce from the mean equinox of date to the true equinox of date. The effect of the short-period terms may be removed, if desired, by subtracting  $f'$ . The formulæ used are

$$\text{Long-period terms} = \frac{1}{15} \Delta\psi \cos \epsilon$$

$$\text{Short-period terms} = f' = \frac{1}{15} d\psi \cos \epsilon = mA'$$

where  $\Delta\psi$  and  $d\psi$  are the long-period and short-period terms respectively of the nutation in longitude.

For star reductions nutation is combined with precession, and computed by means of the Besselian or the independent day numbers.

The *Transit of the First Point of Aries* is the mean time of sidereal  $0^h$ , or the moment when the true equinox is on the meridian. It is computed as the mean time equivalent of  $(24^h - \text{sidereal time at } 0^h)$ ; this formula neglects the change in nutation from  $0^h$  till the time of transit, and thus may be in error by  $0^s\cdot004$ . The effect of short-period terms, which may attain  $\pm 0^s\cdot020$ , is not included. Its use in converting a given sidereal time into mean time is illustrated in Table IV, page 719.

#### *Sun at Transit at Greenwich* (Pages 22-29)

These pages give the Greenwich mean time, together with the apparent right ascension, apparent declination, and semi-diameters of the Sun at apparent noon at Greenwich. A transit ephemeris for any other longitude can be readily made by interpolation, the interpolated G.M.T. becoming the local mean time of transit.

The G.M.T. of transit, i.e. apparent noon, is

$$12^h - \text{equation of time, interpolated to apparent noon.}$$

As the quantity we are seeking is involved in the equation by which it is defined, successive approximations are necessary. Actually, however, it suffices to interpolate the equation of time to the time of apparent noon four years previously, as this time is always within  $3^s$  of the truth for the year under consideration. Hence, if  $F$  is the fraction of the day between  $0^h$  and apparent noon, using the value of  $F$  as determined four years previously

$$\text{E.T. at apparent noon} = \text{E.T. at } 0^h + F\Delta' - 0\cdot0625(\Delta_0'' + \Delta_1'')$$

From this value of the equation of time  $F$  is computed accurately, and then

$$\alpha = \alpha \text{ at } 0^h + F\Delta' - 0\cdot0625(\Delta_0'' + \Delta_1'')$$

$$\delta = \delta \text{ at } 0^h + F\Delta' - 0\cdot0625(\Delta_0'' + \Delta_1'')$$

The semi-diameter in arc is taken as being half-way between the midnight values. The semi-diameter in seconds of sidereal time, or the sidereal time required for the semi-diameter to pass the meridian, is

$$\frac{\text{S. D. in arc} \times \sec \delta \times 86636.555}{15 \times (86636.555 - \Delta\alpha)}$$

$$= \text{S. D. in arc} \times \sec \delta \times S$$

where  $\Delta\alpha$  is strictly the daily variation of  $\alpha$  at the moment of transit, but may be taken as the first difference of the values of  $\alpha$  at 0<sup>h</sup>. 86636.555 is the number of sidereal seconds in one mean solar day. The factor  $S$  has been tabulated in the form of a short critical table with argument  $\Delta\alpha$ .

*Sun's Co-ordinates* (Pages 30-37 and 46-53)

The *Sun's Equatorial Rectangular Co-ordinates* are given for every midnight, together with their first and second differences.

The axis of  $X$  is directed to the first point of Aries, the axis of  $Y$  to the point in the equator whose R.A. is 6<sup>h</sup>, and the axis of  $Z$  to the north pole of the equator.

The co-ordinates on pages 30-37 are referred to the mean equator and equinox of the beginning of the current year. The reduction to the true equinox of date is not given, as co-ordinates referred to that equinox are no longer in use. These co-ordinates will not be published in the *Almanacs* for 1938 and subsequent years, but the co-ordinates referred to the equinox of 1950.0 will be retained. Attention is drawn to the use of the Everett coefficients on pages 747-748 for interpolating these co-ordinates.

$$X = R \cos \lambda$$

$$Y = R (\sin \lambda \cos \epsilon - \sin \beta \sin \epsilon)$$

$$Z = R (\sin \lambda \sin \epsilon + \sin \beta \cos \epsilon)$$

Replacing  $\sin \beta$  by  $\beta \sin 1''$  ( $\beta$  being in seconds) and expressing  $\sin \epsilon \sin 1''$  and  $\cos \epsilon \sin 1''$  in units of the seventh decimal,

$$X = R \cos \lambda$$

$$Y = R (\sin \lambda \cos \epsilon - 19.3 \beta)$$

$$Z = R (\sin \lambda \sin \epsilon + 44.5 \beta)$$

Co-ordinates referred to the equinox of any year may be reduced to the equinox of the following year by

$$\Delta X = -0.000\ 2235\ Y - 0.000\ 0972\ Z$$

$$\Delta Y = +0.000\ 2235\ X$$

$$\Delta Z = +0.000\ 0972\ X$$

The constants  $A_x$ ,  $B_x$ , etc. (see *Planetary Co-ordinates*, page 154) in

$$x = A_x (\cos E - e) + B_x \sin E \text{ etc.}$$

may be reduced by the same coefficients. For reduction from the equinox of any year to that of the preceding year, the signs of the above corrections must be reversed.

The co-ordinates may be reduced to other equinoxes by the formulæ

$$X = X_0 X_0 + Y_0 Y_0 + Z_0 Z_0$$

$$Y = X_0 X_0 + Y_0 Y_0 + Z_0 Z_0$$

$$Z = X_0 X_0 + Y_0 Y_0 + Z_0 Z_0$$

where  $X_0$ ,  $Y_0$ ,  $Z_0$  are the values at the initial epoch, and  $X$ ,  $Y$ ,  $Z$  the values at the final epoch.

$$\begin{aligned}
 X_z &= \cos \zeta_0 \cos z \cos \theta - \sin \zeta_0 \sin z \\
 Y_z &= -\cos \zeta_0 \sin z - \sin \zeta_0 \cos z \cos \theta \\
 Z_z &= -\cos z \sin \theta \\
 X_y &= \sin \zeta_0 \cos z + \cos \zeta_0 \sin z \cos \theta \\
 Y_y &= \cos \zeta_0 \cos z - \sin \zeta_0 \sin z \cos \theta \\
 Z_y &= -\sin z \sin \theta \\
 X_x &= \cos \zeta_0 \sin \theta \\
 Y_x &= -\sin \zeta_0 \sin \theta \\
 Z_x &= \cos \theta
 \end{aligned}$$

For definitions of  $\zeta_0$ ,  $z$  and  $\theta$  see page 786. The numerical values for reduction from the equinox of 1950.0 to the equinoxes of 1900.0, 1925.0, 1975.0 and 2000.0 yield the following series in which  $T$  is reckoned in tropical centuries from 1950.0.

$$\begin{aligned}
 X_x &= 1.0000\ 0000 - 0.0002\ 9696\ T^2 - 0.0000\ 0014\ T^3 \\
 Y_x &= -X_y = -0.0223\ 4941\ T - 0.0000\ 0676\ T^2 + 0.0000\ 0221\ T^3 \\
 Z_x &= -X_z = -0.0097\ 1691\ T + 0.0000\ 0206\ T^2 + 0.0000\ 0098\ T^3 \\
 Y_y &= 1.0000\ 0000 - 0.0002\ 4975\ T^2 - 0.0000\ 0015\ T^3 \\
 Y_x &= Z_y = -0.0001\ 0858\ T^2 \\
 Z_x &= 1.0000\ 0000 - 0.0000\ 4721\ T^2 + 0.0000\ 0002\ T^3
 \end{aligned}$$

The transformation formulæ may also be written

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} X_0 \\ Y_0 \\ Z_0 \end{pmatrix} \begin{pmatrix} X_x & X_y & X_z \\ Y_x & Y_y & Y_z \\ Z_x & Z_y & Z_z \end{pmatrix}$$

in which the multiplications are to be made column by column. The numerical values for 1900–1940 are given in *Planetary Co-ordinates*, Table V, page 107; values for certain special cases are

$$\begin{aligned}
 \begin{pmatrix} X_{1900} \\ Y_{1900} \\ Z_{1900} \end{pmatrix} &= \begin{pmatrix} X_{1950} \\ Y_{1950} \\ Z_{1950} \end{pmatrix} \begin{pmatrix} +0.9999\ 2578 & -0.0111\ 7274 & -0.0048\ 5885 \\ +0.0111\ 7274 & +0.9999\ 3758 & -0.0000\ 2714 \\ +0.0048\ 5885 & -0.0000\ 2714 & +0.9999\ 8820 \end{pmatrix} \\
 \begin{pmatrix} X_{1925} \\ Y_{1925} \\ Z_{1925} \end{pmatrix} &= \begin{pmatrix} X_{1950} \\ Y_{1950} \\ Z_{1950} \end{pmatrix} \begin{pmatrix} +0.9999\ 8144 & -0.0055\ 8690 & -0.0024\ 2934 \\ +0.0055\ 8690 & +0.9999\ 8439 & -0.0000\ 0679 \\ +0.0024\ 2934 & -0.0000\ 0679 & +0.9999\ 9705 \end{pmatrix} \\
 \begin{pmatrix} X_{1930} \\ Y_{1930} \\ Z_{1930} \end{pmatrix} &= \begin{pmatrix} X_{1950} \\ Y_{1950} \\ Z_{1950} \end{pmatrix} \begin{pmatrix} +0.9999\ 8812 & -0.0044\ 6959 & -0.0019\ 4346 \\ +0.0044\ 6959 & +0.9999\ 9001 & -0.0000\ 0434 \\ +0.0019\ 4346 & -0.0000\ 0434 & +0.9999\ 9811 \end{pmatrix} \\
 \begin{pmatrix} X_{1935} \\ Y_{1935} \\ Z_{1935} \end{pmatrix} &= \begin{pmatrix} X_{1950} \\ Y_{1950} \\ Z_{1950} \end{pmatrix} \begin{pmatrix} +0.9999\ 9332 & -0.0033\ 5225 & -0.0014\ 5758 \\ +0.0033\ 5225 & +0.9999\ 9438 & -0.0000\ 0244 \\ +0.0014\ 5758 & -0.0000\ 0244 & +0.9999\ 9894 \end{pmatrix}
 \end{aligned}$$

The values for reduction from the equinox of 1950.0 to that of any other year may also be used for reduction to the equinox of 1950.0 with the following formula

$$\begin{pmatrix} X_{1950} \\ Y_{1950} \\ Z_{1950} \end{pmatrix} = \begin{pmatrix} X_0 \\ Y_0 \\ Z_0 \end{pmatrix} \begin{pmatrix} +X_x & -X_y & -X_z \\ -Y_x & +Y_y & +Y_z \\ -Z_x & +Z_y & +Z_z \end{pmatrix} = \begin{pmatrix} X_0 \\ Y_0 \\ Z_0 \end{pmatrix} \begin{pmatrix} X_x & Y_x & Z_x \\ X_y & Y_y & Y_z \\ X_z & Y_z & Z_z \end{pmatrix}$$

in which  $X_0$ ,  $Y_0$  and  $Z_0$  are, as above, the known values at the initial epoch.

The same numerical coefficients may be used for the reduction of  $A_x$ ,  $B_x$ , etc.

*Sun, referred to Mean Equinox of 1950.0 (Pages 38–45)*

The Sun's *Longitude and Latitude* are given both in degrees and decimals of a degree and in degrees, minutes and seconds.

The natural value of the *Radius Vector* given here corresponds to the logarithmic value on pages 7-21; it is, of course, independent of the equinox.

The longitude is obtained by adding to the longitude for the mean equinox of 1935.0 the quantity  $a$  on page 54. The latitude for the mean ecliptic of 1935.0 is reduced to the mean ecliptic of 1950.0 by the addition of  $b \sin(\lambda_0 + c)$ , where  $\lambda_0$  is the longitude for 1935.0, and  $b$  and  $c$  are given on page 54.

For the correction to the Sun's co-ordinates depending on an assumed correction to the mean longitude, see page 775.

#### Sun (Page 54)

The *Horizontal Parallax* is the angle subtended at the Sun by the Earth's equatorial radius. The adopted value at unit distance is  $8''.80$ , so that the tabulated value is  $8''.80 \div R$ .

The *Aberration* is the movement in longitude of the Sun during the time taken by light to reach the Earth from the Sun. The apparent longitude is always less than the true geometrical longitude by the amount of the aberration, because the position in which an observer sees the Sun is that which it really occupied about  $8^m$  earlier, when the observed light left the Sun. The adopted constant of aberration is  $20''.47$ , and the value tabulated is  $20''.47 \div R$ .

The *Elements of the Sun*, as given by Newcomb in his *Tables of the Sun*, are

$$\begin{aligned} \text{Epoch 1900 January 0.0 G.M.T.} &= \text{J.D. } 2415020.0 \\ L &= 279^\circ 41' 48''.04 + 129602768''.13 T + 1''.089 T^2 \\ &= 279^\circ 49' 66.68 + 0^\circ 9856473354 d + 0^\circ 000302 T^2 \\ \pi^* &= 281^\circ 13' 15''.0 + 6189''.03 T + 1''.63 T^2 + 0''.012 T^3 \\ &= 281^\circ 22' 08.3 + 0^\circ 0000470684 d + 0^\circ 000453 T^2 + 0^\circ 000003 T^3 \\ g &= L - \pi = 358^\circ 28' 33''.0 + 129596579''.10 T - 0''.54 T^2 - 0''.012 T^3 \\ &= 358^\circ 47' 58.3 + 0^\circ 9856002670 d - 0^\circ 000150 T^2 - 0^\circ 000003 T^3 \\ e &= 0.01675104 - 0.00004180 T - 0.000000126 T^2 \\ \epsilon &= 23^\circ 27' 08''.26 - 46''.845 T - 0''.0059 T^2 + 0''.00181 T^3 \\ &= 23^\circ 45' 22.94 - 0^\circ 0130125 T - 0^\circ 00000164 T^2 + 0^\circ 000000503 T^3 \end{aligned}$$

where  $T$  is measured in Julian centuries of 36525 days, and  $d$  in days. The mean longitude  $L$  is measured from the mean equinox of date. The right ascension of the mean sun is given on page 780.

From the above mean motions the lengths of the three principal years are

$$\begin{array}{lll} \text{Tropical} & \dots & 365^\circ 242' 19.879 - 0.00000614 T \\ \text{Sidereal} & \dots & 365^\circ 256' 36.042 + 0.00000011 T \\ \text{Anomalistic} & \dots & 365^\circ 259' 64.134 + 0.00000304 T \end{array}$$

The logarithm of the mean distance  $a$  as computed by the expression

$$a^3 n^2 = k^2 (1 + m)$$

where

$$\begin{aligned} n &= \text{mean daily motion of the Sun} \\ k &= \text{Gaussian gravitational constant} \\ &= 0.01720209895 = 3548''.18761 \\ m &= \text{mass of Earth + Moon} = 1 \div 329390 \end{aligned}$$

\* The notation used here is that of Newcomb's *Tables*; elsewhere in this *Almanac* the mean longitude of the Sun's perigee is denoted by  $\Gamma$ .

is 0.000000013, to which have been added corrections due to the action of the planets, so that the value adopted in the tables is 0.00000010.

The existence of a term in  $T^2$  in the right ascension of the mean sun may cause surprise, when it is remembered that the mean sun is defined as having a *uniform* motion in the equator. Actually the motion is uniform, but in the expression of its numerical value it is measured from the mean equinox, which has a secular or  $T^2$  term. Hence the linear or  $T$  term of the right ascension of the mean sun agrees with that of the mean longitude of the true Sun, while the secular term of the right ascension of the mean sun is that of the mean equinox, and differs by  $0''.305 T^2$  or  $0^s.0203 T^2$  from that of the mean longitude of the true Sun. Speaking of this, Newcomb, in his *Astronomical Constants*, page 188, says "This difference is of no importance in the astronomy of our time, but may result in an error of  $2^s$  in the course of 1000 years in the measurement of time by the actual mean sun. We must leave to the astronomers of the future the question how best to meet the question thus arising."

#### Precessional Constants (Page 54)

The geometrical significance of the various constants may be understood by reference to the diagram, in which  $Q_0$ ,  $E_0$  and  $C_0$  represent the equator, ecliptic and equinox at some initial epoch  $t_0$ , and  $Q$ ,  $E$  and  $C$  at the epoch  $t$ .  $M$  is the node of the two equators, and  $N$  that of the two ecliptics, these nodes being the ascending ones if  $t - t_0$  is positive.  $C_1$  is the intersection of the initial ecliptic and the equator of date.

$$\epsilon_0 = E_0 C_0 Q_0 \quad \epsilon = ECQ \quad \epsilon_1 = E_0 C_1 Q$$

If the interval between the two epochs is one year

$$\psi = \text{luni-solar precession} = C_1 C_0$$

$$\lambda = \text{planetary precession on the equator} = C_1 C$$

$$p = \text{general precession in longitude} = CN - C_0 N = \psi - \lambda \cos \epsilon_1$$

$$m = \text{general precession in R.A.} = CM - C_0 M = \psi \cos \epsilon_1 - \lambda$$

$$n = \text{precession in declination} = C_0 MC$$

$$\pi = \text{inclination of moving ecliptic to fixed ecliptic} = C_0 NC = \text{speed of rotation of ecliptic}$$

If the interval between the two epochs is  $t - t_0$  years

$\Pi$  = ascending node of moving ecliptic on fixed ecliptic =  $C_0N$

$\zeta_0 = 90^\circ - C_0M$      $\zeta = 90^\circ - C_1M$      $z = CM - 90^\circ$

$\theta$  = inclination of moving equator to fixed equator =  $C_0MC$

$M$  = general precession in R.A. =  $CM - C_0M = \zeta_0 + z = \bar{m} (t - t_0)$

$N$  = precession in declination =  $C_0MC = \theta = \bar{n} (t - t_0)$

$a$  = general precession in longitude =  $CN - C_0N = \bar{p} (t - t_0)$

$b$  = inclination of moving ecliptic to fixed ecliptic =  $C_0NC = \bar{\pi} (t - t_0)$

$c = 180^\circ - \Pi + \frac{1}{2}a$

The following values are given by Newcomb,  $T$  being measured in tropical centuries from 1900.0:—

$$\begin{aligned}\text{Annual luni-solar precession} &= \psi = 50''.3708 + 0''.0050 T \\ \text{Annual planetary precession on equator} &= \lambda = 0''.1248 - 0''.0188 T \\ \text{Annual general precession} &= p = 50''.2564 + 0''.0222 T \\ \text{Annual precession in R.A.} &= m = 3''.07234 + 0''.00186 T \\ \text{Annual precession in Dec.} &= n = 20''.0468 - 0''.0085 T \\ &= 1''.33646 - 0''.00057 T\end{aligned}$$

$$\text{Obliquity} = \epsilon = 23^\circ 27' 08''.26 - 46''.845 T - 0''.0059 T^2 + 0''.00181 T^3$$

$$\Pi = 173^\circ 57'.06 + 54'.77 T$$

$$\pi = 0''.4711 - 0''.0007 T$$

$$\zeta_0 = 2304.25 T + 0.30 T^2 + 0.018 T^3$$

$$z = 2304.25 T + 1.09 T^2 + 0.019 T^3$$

$$\theta = 2004.68 T - 0.43 T^2 - 0.041 T^3$$

The values of  $\epsilon$ ,  $p$ ,  $m$ ,  $n$ ,  $\Pi$  and  $\pi$  on page 54 are derived from the above formulæ by putting  $T = 0.35$ .

The formulæ used for the quantities  $\zeta_0$ ,  $z$  and  $\theta$ , for reduction from the equinox of 1950.0 to the mean equinox of other years are

$$\zeta_0 = 2304.948 T + 0.302 T^2 + 0.0179 T^3$$

$$z = 2304.948 T + 1.093 T^2 + 0.0192 T^3$$

$$\theta = 2004.255 T - 0.426 T^2 - 0.0416 T^3$$

where  $T$  is measured from 1950.0 in tropical centuries. For reduction to the equinox of 1950.0,  $\zeta_0$  must be replaced by  $-z$ ,  $z$  by  $-\zeta_0$  and  $\theta$  by  $-\theta$ .

The formulæ for  $M$ ,  $N$ ,  $a$ ,  $b$  and  $c$  are:—

For reduction from the equinox of  $t$  to that of 1950.0

$$M = \zeta_0 + z = \bar{m} (1950.0 - t)$$

$$N = \theta = \bar{n} (1950.0 - t)$$

$$a = \bar{p} (1950.0 - t)$$

$$b = \bar{\pi} (1950.0 - t)$$

$$c = 180^\circ - \Pi + \frac{1}{2}a$$

and for reduction from the equinox of 1950.0 to that of  $t$

$$M = \zeta_0 + z = \bar{m} (t - 1950.0)$$

$$N = \theta = \bar{n} (t - 1950.0)$$

$$a = \bar{p} (t - 1950.0)$$

$$b = \bar{\pi} (t - 1950.0)$$

$$c = 180^\circ - \Pi - \frac{1}{2}a$$

where  $\bar{m}$ ,  $\bar{n}$ ,  $\bar{p}$ ,  $\bar{\pi}$  and  $\bar{\Pi}$  are the values of  $m$ ,  $n$ ,  $p$ ,  $\pi$  and  $\Pi$  at the epoch half-way between 1950.0 and  $t$ .

Values of the precessional elements for the years 1800–1950 are given in Tables I–IV of *Planetary Co-ordinates*.

For reduction from the equinox of any year to that of the succeeding year, the following simplified formulæ may be used

$$\begin{aligned}\Delta\lambda &= +50''.27 - 0''.47 \cos(\lambda + 6^\circ) \tan \beta \\ \Delta\beta &= +0''.47 \sin(\lambda + 6^\circ) \\ \Delta\alpha &= +38''.073 + 18''.336 \sin \alpha \tan \delta \\ \Delta\delta &= +20''.04 \cos \alpha \\ \Delta\Omega &= +50''.27 - 0''.47 \sin(\Omega + 6^\circ) \cot i \\ &= +0''.01396 - 0''.00013 \sin(\Omega + 6^\circ) \cot i \\ \Delta i &= +0''.47 \cos(\Omega + 6^\circ) = +0''.00013 \cos(\Omega + 6^\circ) \\ \Delta\omega &= +0''.47 \sin(\Omega + 6^\circ) \operatorname{cosec} i \\ &= +0''.00013 \sin(\Omega + 6^\circ) \operatorname{cosec} i\end{aligned}$$

For reduction from the equinox of any year to that of the preceding year, the signs of the above corrections must be reversed.

The formulæ for the rigorous reduction of star positions from one epoch to another are

$\alpha_0$ ,  $\delta_0$  = R.A. and Dec. for equinox  $t_0$  and epoch  $t$ , i.e. the proper motion for the interval  $t - t_0$  is *first* applied

$$\begin{aligned}a &= \alpha_0 + \zeta_0 \\ \cos \delta \sin a' &= \cos \delta_0 \sin a \\ \cos \delta \cos a' &= \cos \theta \cos \delta_0 \cos a - \sin \theta \sin \delta_0 \\ \sin \delta &= \sin \theta \cos \delta_0 \cos a + \cos \theta \sin \delta_0 \\ a &= a' + z\end{aligned}$$

or, if the star is not too near the pole

$$\begin{aligned}a &= \alpha_0 + \zeta_0 \\ p &= \sin \theta (\tan \delta_0 + \tan \frac{1}{2}\theta \cos a) \\ \tan(a' - a) &= \frac{p \sin a}{1 - p \cos a} \\ a &= a + (a' - a) + z = \alpha_0 + (a' - a) + M \\ \tan \frac{1}{2}(\delta - \delta_0) &= \frac{\cos \frac{1}{2}(a' + a)}{\cos \frac{1}{2}(a' - a)} \tan \frac{1}{2}\theta\end{aligned}$$

The formulæ at the foot of page 54 for reducing right ascension and declination may be used if an approximate precession is known to determine  $\bar{\alpha}$  and  $\bar{\delta}$ . Another rigorous form of reduction, intended for use when accurate precessions and secular variations are not available, is given in Tables XIII and XIV, pages 730–734.

The formulæ on page 54, for the reduction of longitude, latitude and orbital elements from 1935.0 to 1950.0 or vice versa, may be regarded as rigorous.

#### *Moon's Mean Equator, Orbit and Mean Longitude (Page 55)*

The quantities given are

- $i$  = inclination of the Moon's mean equator to the Earth's true equator
- $\Delta$  = distance on the Moon's mean equator from its ascending node on the Earth's true equator to its ascending node on the ecliptic

$\Omega'$  = distance in the Earth's true equator from the true equinox to the ascending node of the Moon's mean equator

$\Gamma'$  = mean longitude of the Moon's perigee measured in the ecliptic from the mean equinox to the mean ascending node of the Moon's orbit, and then in the Moon's orbit

$\Omega$  = longitude of the mean ascending node of the Moon's orbit on the ecliptic, measured from the mean equinox

$\epsilon$  = mean longitude of the Moon, measured in the ecliptic from the mean equinox to the mean ascending node of the Moon's orbit, and then in the Moon's orbit.

The ascending node of the Moon's equator on the ecliptic is also the descending node of the Moon's orbit on the ecliptic, i.e.  $\Omega \pm 180^\circ$ .

If

$I$  = the constant inclination of the Moon's mean equator to the ecliptic  
=  $1^\circ 32' \cdot 1$  according to Hayn (page 819)

$\epsilon$  = true obliquity

$N$  = nutation in longitude

then

$$\cos i = \cos I \cos \epsilon + \sin I \sin \epsilon \cos(\Omega + N)$$

$$\sin \Omega' = -\sin(\Omega + N) \operatorname{cosec} i \sin I$$

$$\sin \Delta = -\sin(\Omega + N) \operatorname{cosec} i \sin \epsilon$$

$$\text{or } \cos \Delta = -\cos(\Omega + N) \cos \Omega' - \sin(\Omega + N) \sin \Omega' \cos \epsilon$$

The quadrant of  $\Delta$  is determined from the sign of  $\sin \Delta$  or  $\cos \Delta$ , whichever is used, and the fact that  $\Delta$  is always approximately  $\Omega + N \pm 180^\circ$ .

The fundamental elements in Brown's *Tables of the Motion of the Moon*, Section I, Chapter I, page 28, are

Epoch 1900 January 0.0 G.M.T. = J.D. 241 5020.0

$$\epsilon = 270^\circ 26' 11 \cdot 71 + 481267^\circ 53' 26 \cdot 06 T + 7 \cdot 14 T^2 + 0 \cdot 0068 T^3$$

$$\Gamma' = 334 19 46 \cdot 40 + 4069 02 02 \cdot 52 T - 37 \cdot 17 T^2 - 0 \cdot 045 T^3$$

$$\Omega = 259 10 59 \cdot 79 - 1934 08 31 \cdot 23 T + 7 \cdot 48 T^2 + 0 \cdot 008 T^3$$

$$e = \text{eccentricity} = 0 \cdot 054900489$$

$$\gamma = \sin \frac{1}{2} i = 0 \cdot 044886967$$

$$\text{Constant term in sine parallax} = 3422 \cdot 5400$$

$$\text{Ratio of mass of Earth to mass of Moon} = 81 \cdot 53$$

In the above  $T$  is measured in Julian centuries of 36525 days. If  $d$  is measured in days from the epoch

$$\epsilon = 270^\circ 436586 + 13 \cdot 1763967302 d + 0 \cdot 001983 T^2 + 0 \cdot 0000019 T^3$$

$$\Gamma' = 334 \cdot 329556 + 0 \cdot 1114040803 d - 0 \cdot 010325 T^2 - 0 \cdot 000012 T^3$$

$$\Omega = 259 \cdot 183275 - 0 \cdot 0529539222 d + 0 \cdot 002078 T^2 + 0 \cdot 000002 T^3$$

### Moon (Pages 56-71)

The Moon's *Longitude* and *Latitude* are taken from Brown's *Tables of the Motion of the Moon*, and are referred to the true ecliptic and equinox of date, but with the omission of the short-period terms of nutation in longitude. In these quantities no correction is made to Brown's *Tables*, but see also page 775 and under *Eclipses* and *Occultations*.

The Moon's *Horizontal Parallax*, or the angle subtended at the Moon's centre by the Earth's equatorial radius, is also taken from Brown's *Tables*.

The distance of the Moon is

$$\frac{\text{Earth's equatorial radius}}{\text{sine of Moon's horizontal parallax}}$$

which, using Hayford's value of 3963.34 miles for the Earth's equatorial radius, may be taken as

$$\text{Distance in miles} = \frac{817,535,000}{\text{H.P. in seconds of arc}}$$

The Moon's *Semi-diameter*,  $s$ , is derived from the horizontal parallax,  $\pi$ , by the relation

$$\frac{\sin s}{\sin 15' 32'' \cdot 58} = \frac{\sin \pi}{\sin 57' 02'' \cdot 70}$$

where  $15' 32'' \cdot 58$  is the semi-diameter at mean distance as given by Newcomb and  $57' 02'' \cdot 70$  is the mean equatorial horizontal parallax as given by Brown.

This leads to

$$\sin s = 0.272481 \sin \pi$$

or, with an error not exceeding  $0''.001$ ,

$$s = 0''.079 + 0.272446 \pi$$

No correction is made for irradiation.

The Moon's *Age*, given for every midnight, is the number of days elapsed since the previous New Moon.

The times of the *Moon's Upper and Lower Transits over the Meridian of Greenwich* are given, and are for the centre of the Moon; interpolation to any given longitude will yield the local mean time of transit.

#### *Moon's Right Ascension and Declination (Pages 72-163)*

The *Moon's Right Ascension and Declination* are referred to the true equator and equinox, but with the omission of short-period terms of nutation.

The noon and midnight values are found from the longitude and latitude obtained from Brown's *Tables*. The formulæ for conversion are

$$\begin{aligned} \cos \delta \cos \alpha &= \cos \beta \cos \lambda \\ \cos \delta \sin \alpha &= \cos \beta (\sin \lambda \cos \epsilon - \tan \beta \sin \epsilon) \\ \sin \delta &= \cos \beta (\sin \lambda \sin \epsilon + \tan \beta \cos \epsilon) \end{aligned}$$

so that

$$\tan \alpha = \frac{\sin \lambda \cos \epsilon - \tan \beta \sin \epsilon}{\cos \lambda}$$

or

$$\cot \alpha = \frac{\cos \lambda}{\sin \lambda \cos \epsilon - \tan \beta \sin \epsilon}$$

It is convenient to determine  $\tan \alpha$  or  $\cot \alpha$ , whichever is numerically less than 1.

The interpolation of the half-daily values to hourly values is done by the method described in Brown's *Tables*, Section I, Chapter VIII.

*Phases of the Moon (Page 163)*

The times of New Moon, First Quarter, Full Moon and Last Quarter are the Greenwich mean times when the excess of the Moon's longitude (pages 56-71) over the Sun's apparent longitude is  $0^\circ$ ,  $90^\circ$ ,  $180^\circ$  and  $270^\circ$  respectively. On account of the inclination of the Moon's orbit to the ecliptic the time of New Moon may differ slightly from the time of closest approach of the Sun and Moon.

The times of the Moon's *Perigee* and *Apogee* are the times when the Moon attains its least and greatest distances respectively from the Earth, i.e. when the horizontal parallax attains its maxima and minima respectively.

*Moon at Transit at Greenwich (Pages 164-179)*

This ephemeris, in common with other transit ephemerides, may be reduced to any other longitude by interpolation.

The column *Illuminated Limbs and Transit* shows the limbs, north or south, and I (preceding or west) or II (following or east), that are fully illuminated at the moment of transit at Greenwich. The indication for north or south limb is given only for upper transit at Greenwich, and is omitted when the transit occurs between  $9^h$  and  $15^h$  G.M.T., i.e. when the Moon is too close to the Sun for observation.

The *Apparent Geocentric Right Ascension of the Centre* may be reduced to the apparent right ascension of the limb by applying the quantity given in the next column.

The *Sidereal Time of Semi-diameter passing the Meridian* is the interval, in sidereal time, between the time of transit of the Moon's centre and the transit of the limb. Hence

$$\begin{aligned}\text{R.A. of Moon's centre} &= \text{R.A. of limb I} + \text{S.D. in time} \\ &= \text{R.A. of limb II} - \text{S.D. in time}.\end{aligned}$$

The *Apparent Geocentric Declination of the Centre* must be corrected for parallax before being compared with a meridian observation, or, alternatively, a correction  $\Delta\delta$  must be applied to the observed declination  $\delta'$  of the centre to render it comparable with the geocentric declination  $\delta$ . This correction is given by

$$\begin{aligned}\sin \Delta\delta &= -\rho \sin \pi \sin(\phi' - \delta') \\ \text{or} \quad \Delta\delta &= -0.999957 \rho \pi \sin(\phi' - \delta') \\ \text{or} \quad \tan \Delta\delta &= -\frac{\rho \sin \pi \sin(\phi' - \delta)}{1 - \rho \sin \pi \cos(\phi' - \delta)}\end{aligned}$$

where

$$\begin{aligned}\pi &= \text{horizontal parallax} \\ \rho &= \text{geocentric radius} \\ \phi' &= \text{geocentric latitude}.\end{aligned}$$

The *Geocentric Semi-diameter* must be corrected for augmentation before being used to reduce an observed declination of the northern or southern limb to the declination of the centre.

$$\begin{aligned}\text{If} \quad s &= \text{geocentric semi-diameter} \\ s' &= \text{augmented semi-diameter}\end{aligned}$$

then

$$s' = \frac{s \sin(\phi' - \delta')}{\sin(\phi' - \delta)}$$

in which we may put, with sufficient accuracy,

$$\delta' = \delta - \rho \pi \sin(\phi' - \delta)$$

or, rigorously,

$$\delta' = \delta + \Delta\delta$$

$\Delta\delta$  being defined in the preceding paragraph.

The *Equatorial Horizontal Parallax* is the geocentric value (as on pages 56-71) interpolated to the time of transit at Greenwich.

At certain times when the east point of the Moon is fully illuminated the west point is nearly so, and vice versa; similarly for the north and south points. If the defect of illumination is not too great it is possible to observe two opposite limbs, the observation of one being really an observation of the terminator and not of the limb, and being corrected by the amount of the *Defective Illumination*, as given in the footnotes. It must be emphasised that the values given for defective illumination, as well as the indications for illuminated limbs, apply only to transit at Greenwich, and not to other observatories. They are derived as follows.

- Let  $\alpha$  = R.A. of Moon's centre  
 $\delta$  = geocentric declination of Moon's centre  
 $\delta'$  = apparent declination of Moon's centre =  $\delta - \pi \sin(\phi - \delta)$   
 $\alpha_0$ ,  $\delta_0$  = Sun's right ascension and declination  
 $\pi$  = Moon's horizontal parallax  
 $S$  = sidereal time of semi-diameter passing meridian  
 $s$  = geocentric semi-diameter  
 $\phi$  = geographical latitude

the variable quantities being interpolated to the time of transit. Then, if  $\theta$  is the altitude of the Sun above the horizon for an observer at the north point of the Moon's disc,

$$\sin \theta = \sin \delta_0 \cos \delta' - \cos \delta_0 \sin \delta' \cos(\alpha - \alpha_0)$$

If  $\theta$  is positive the north limb is full and the correction for defective illumination is to be applied to the south limb, and vice versa. If the time of transit is before the time of Full Moon limb I is full and the correction for defective illumination is to be applied to limb II, and vice versa.

$$\begin{aligned} \text{Defective illumination in R.A.} &= \frac{1}{2} S \sin^2(\alpha - \alpha_0) \cos^2 \delta_0 \\ \text{Defective illumination in Dec.} &= s(1 - \cos \theta) = \frac{1}{2} s \sin^2 \theta \end{aligned}$$

The defective illumination in R.A. is given only when  $\alpha - \alpha_0$  at transit lies between  $11^{\text{h}} 40^{\text{m}}$  and  $12^{\text{h}} 20^{\text{m}}$ , and the defective illumination in declination when  $\theta$  is less than  $3^\circ$ .

#### *Heliocentric Longitudes, Latitudes and Radii Vectores of Planets*

The heliocentric places, which are referred to the mean equinox of date, are from the Tables of Newcomb and Hill in the *Astronomical Papers of the American Ephemeris and Nautical Almanac*.

The heliocentric longitude and latitude and the logarithm of the radius vector of Mercury are given each year in the *Nautical Almanac* (pages 180-183 in 1935). Before 1931 these quantities were given for Greenwich mean noon; they are now, in common with the other quantities in the *Almanac*, given for mean midnight.

The corresponding data for Venus are given for 1916-1918 in an appendix to the *Nautical Almanac* for 1915, and for 1919-1940 in an appendix to the issue

for 1916. For Mars the values for 1916-1918 are given in the appendix to the *Nautical Almanac* for 1915, and for 1919-1940 in an appendix to the issue for 1917; Ross's corrections are given in an appendix to the *Almanac* for 1920. For Jupiter, Saturn, Uranus and Neptune the values for 1916-1940 are given in the appendix to the *Nautical Almanac* for 1915.

Heliocentric places, referred to the standard equinox of 1950.0, are given in *Planetary Co-ordinates* (see page 777).

*Planets at 0<sup>h</sup> (Pages 184-239)*

The *Apparent Right Ascension* and *Declination* are referred to the true equator and equinox of date, and are corrected for planetary aberration. The short-period terms of nutation are not included.

The adopted *Semi-diameters* at unit distance, and the authority for each, are

Mercury	3.34	Le Verrier
Venus	8.41	Auwers
Mars	4.68	Hartwig
Jupiter (Equatorial)	98.47	Sampson
Jupiter (Polar)	91.91	Sampson
Saturn (Equatorial)	83.33	Struve
Saturn (Polar)	74.57	Struve
Uranus	34.28	Barnard, See, Wirtz
Neptune	36.56	Barnard

The *Horizontal Parallaxes* are based on a parallax at unit distance of 8".80.

In the *Logarithm of the True Distance from the Earth* the word *true* is used to emphasise the fact that the distance given is the actual distance at 0<sup>h</sup>, and not at the moment when the light that reaches an observer at 0<sup>h</sup> left the planet. In the case of Mercury, the distance from the Earth (not its logarithm) is given.

The time of *Meridian Passage* at Greenwich may be interpolated to give the local mean times of passage over other meridians.

In the formation of the geocentric ephemeris from the heliocentric ephemeris, the following notation and methods are used.

$\lambda_0$  = Sun's longitude, referred to mean equinox of date, not affected by aberration, as given by Newcomb's *Tables*

$\lambda$  = Sun's longitude, referred to true equinox of date =  $\lambda_0$  + nutation in longitude

$\beta$  = Sun's latitude referred to ecliptic of date, as given by Newcomb's *Tables*

$R$  = radius vector of Sun

$l_0$  = heliocentric longitude of planet, referred to mean equinox of date, as given by the tables mentioned on page 791

$l$  = heliocentric longitude of planet, referred to true equinox of date =  $l_0$  + nutation in longitude

$b$  = heliocentric latitude of planet

$r$  = radius vector of planet

$\epsilon$  = apparent obliquity

$\alpha$  = geocentric right ascension of planet

$\delta$  = geocentric declination of planet

$\Delta$  = geocentric distance of planet.

The formulæ used for conversions up to and including 1940 are

$$\tan \psi = \frac{r \cos b \sin(l - \lambda)}{R + r \cos b \cos(l - \lambda)}$$

$$\text{Geocentric longitude} = \lambda + \psi$$

$$\begin{aligned} \text{Geocentric latitude} &= \tan^{-1} \frac{r \sin b \sin \psi}{r \cos b \sin(l - \lambda)} + \frac{R\beta}{\Delta} \\ &= \tan^{-1} \frac{r \sin b \cos \psi}{R + r \cos b \cos(l - \lambda)} + \frac{R\beta}{\Delta} \end{aligned}$$

$$\begin{aligned} \text{Geocentric distance} &= \Delta = r \cos b \sin(l - \lambda) \operatorname{cosec} \psi \sec(\text{geocentric lat.}) \\ &= \{R + r \cos b \cos(l - \lambda)\} \sec \psi \sec(\text{geocentric lat.}) \end{aligned}$$

The first of the alternative formulæ for latitude and distance are used when  $\psi$  is near  $90^\circ$  or  $270^\circ$ , and the second when it is near  $0^\circ$  or  $180^\circ$ .

The planetary aberration, or correction to the planet's position to allow for its motion during the time taken by light to reach the Earth from the planet, is introduced at this stage. As in the case of the Sun (page 780) the necessary correction is  $-0.0028841 \Delta \times \text{motion in } 2^d$ . The motion in  $2^d$  is obtained by subtracting the uncorrected geocentric longitude (or latitude) on the day before that for which the calculation is being made from that on the day following.

Calling  $L$  and  $B$  the corrected geocentric longitude and latitude

$$\begin{aligned} \tan \theta &= \tan B \operatorname{cosec} L \\ \tan \alpha &= \tan L \sec \theta \cos(\theta + \epsilon) \\ \tan \delta &= \sin \alpha \tan(\theta + \epsilon) \end{aligned}$$

The above formulæ have been used in the past with logarithmic calculations, but, in view of the present availability of calculating machines, the following simpler procedure has been adopted.

$$\begin{aligned} X &= R \cos \lambda \\ Y &= R (\sin \lambda \cos \epsilon - 19.3 \beta) \\ Z &= R (\sin \lambda \sin \epsilon + 44.5 \beta) \end{aligned}$$

$\beta$  being in seconds of arc, and the numerical coefficients in units of the seventh decimal. These values are readily formed from quantities already found (see page 779) in the process of converting the Sun's longitude and latitude to right ascension and declination.

$$\begin{aligned} x &= r \cos b \cos l \\ y &= r \cos b (\sin l \cos \epsilon - \tan b \sin \epsilon) \\ z &= r \cos b (\sin l \sin \epsilon + \tan b \cos \epsilon) \\ \Delta \cos \delta_0 \cos \alpha_0 &= \xi = x + X \\ \Delta \cos \delta_0 \sin \alpha_0 &= \eta = y + Y \\ \Delta \sin \delta_0 &= \zeta = z + Z \end{aligned}$$

which are solved thus:—

$$\begin{aligned} \Delta &= \sqrt{\xi^2 + \eta^2 + \zeta^2} \\ \tan \alpha_0 &= \frac{\eta}{\xi} \quad (\text{used if } \eta \text{ is less than } \xi) \\ \cot \alpha_0 &= \frac{\xi}{\eta} \quad (\text{used if } \xi \text{ is less than } \eta) \\ \sin \delta_0 &= \frac{\zeta}{\Delta} \end{aligned}$$

$$\begin{aligned} \alpha &= \alpha_0 - 0.0028841 \Delta \times \text{motion of } \alpha_0 \text{ in } 2^d \\ \delta &= \delta_0 - 0.0028841 \Delta \times \text{motion of } \delta_0 \text{ in } 2^d \end{aligned}$$

It may be remarked that, since this process is to be applied to all the planets, the quantities  $X$ ,  $Y$ ,  $Z$ ,  $\sin \epsilon$  and  $\cos \epsilon$  need be computed once only. The quantities  $\sin \epsilon$  and  $\cos \epsilon$  are also used in the conversion of the Moon's longitude and latitude to right ascension and declination.

For Uranus and Neptune the geocentric ephemeris is computed first at intervals of four days, and then interpolated. This is the maximum possible interval, as the Earth does not move in a purely elliptical orbit round the Sun, having in addition a motion in an orbit round the centre of gravity of the Earth and Moon, the point that moves round the Sun in accordance with Kepler's laws. The period of this subsidiary motion is the lunar tropical month of  $27^d.322$ , so that the motion in four days is  $53^\circ$ . Harmonic terms that move through more than one radian ( $57^\circ.3$ ) in the interval between successive calculations would, if included, result in the failure of the quantities in which they are included to difference properly.

#### *Planets at Transit at Greenwich (Pages 240-261)*

These ephemerides facilitate the reduction of meridian observations of the planets. They may be reduced to any other longitude by interpolation. The right ascensions and declinations are geocentric, are referred to the true equator and equinox of date, are corrected for aberration but not for the short-period terms of nutation, and are for the centre of the planet. For the outer planets the ephemeris is given only when the transit is later than  $16^h$  G.M.T. (or some later limit depending on the time of sunset) or earlier than  $2^h$  G.M.T.

The semi-diameter in arc is computed by interpolation of the values at  $0^h$ . The sidereal time of semi-diameter passing meridian, or the correction required to reduce an observation of a fully-illuminated limb to the centre, is taken as

$$\frac{1}{15} \sec \delta \times \text{semi-diameter in arc}$$

in which a small term depending on the planet's motion in right ascension is regarded as negligible. In the case of Jupiter and Saturn the sidereal times of the equatorial semi-diameter passing the meridian, and the polar semi-diameters, have been calculated on the assumption, only approximately true, that the extremities of the axes of rotation are the north and south points of the discs.

#### *Besselian and Independent Day Numbers (Pages 262-289)*

The formulæ from which these quantities are computed are given below. The constants of precession, nutation and aberration involved are those adopted by the *Conférence Internationale des Etoiles Fondamentales* which met in Paris in 1896.

$L$  = Sun's mean longitude

$\lambda$  = Sun's true longitude, affected by nutation, but not by aberration

$\Gamma$  = mean longitude of the Sun's perigee

$\zeta$  = Moon's mean longitude

$\Omega$  = mean longitude of the Moon's ascending node

$\Gamma'$  = mean longitude of the Moon's perigee

$\epsilon$  = true obliquity

$\tau$  = fraction of the tropical year

$T$  = time from 1900-0, measured in tropical centuries.

*Long-period terms*

$$\begin{aligned}
 A = & \tau - 0.34215 \sin \Omega \\
 & - 0.00031 T \sin \Omega \\
 & + 0.00415 \sin 2\Omega \\
 & - 0.02526 \sin 2L \\
 & + 0.00251 \sin(L - \Gamma) \\
 & - 0.00099 \sin(3L - \Gamma) \\
 & + 0.00042 \sin(L + \Gamma) \\
 & + 0.00025 \sin(2L - \Omega)
 \end{aligned}$$

*Short-period terms*

$$\begin{aligned}
 A' = & -0.00405 \sin 2\ell \\
 & + 0.00134 \sin(\ell - \Gamma') \\
 & - 0.00068 \sin(2\ell - \Omega) \\
 & - 0.00052 \sin(3\ell - \Gamma') \\
 & + 0.00030 \sin(\ell - 2L + \Gamma') \\
 & + 0.00023 \sin(\ell + \Gamma') \\
 & + 0.00012 \sin 2(\ell - L)
 \end{aligned}$$

$$\begin{aligned}
 B = & -9.210 \cos \Omega \\
 & + 0.090 \cos 2\Omega \\
 & - 0.551 \cos 2L \\
 & - 0.022 \cos(3L - \Gamma) \\
 & + 0.009 \cos(L + \Gamma) \\
 & + 0.007 \cos(2L - \Omega)
 \end{aligned}$$

$$\begin{aligned}
 B' = & -0.088 \cos 2\ell \\
 & - 0.018 \cos(2\ell - \Omega) \\
 & - 0.011 \cos(3\ell - \Gamma') \\
 & + 0.005 \cos(\ell + \Gamma')
 \end{aligned}$$

$$C = -20''.47 \cos \epsilon \cos \lambda = -18''.780 \cos \lambda$$

$$D = -20''.47 \sin \lambda$$

$$\begin{aligned}
 E = & \frac{\text{planetary precession}}{\text{luni-solar precession}} \times \text{nutations in longitude} \\
 = & (0.000165 - 0.000025 T) \times \text{nutations in longitude}
 \end{aligned}$$

If

$$\psi = \text{annual luni-solar precession} = 50''.3708 + 0''.0050 T$$

$$\Delta\psi = \text{long-period terms of nutations in longitude}$$

$$d\psi = \text{short-period terms of nutations in longitude}$$

$$\Delta\epsilon = \text{long-period terms of nutations in obliquity}$$

$$d\epsilon = \text{short-period terms of nutations in obliquity}$$

then

$$A = \tau + \frac{\Delta\psi}{\psi} = \tau + \Delta\psi (0.0198528 - 0.0000020 T)$$

$$B = -\Delta\epsilon \quad A' = \frac{d\psi}{\psi} \quad B' = -d\epsilon$$

The independent day numbers are derived from the Besselian day numbers by the following relations:—

$$\begin{aligned}
 f &= mA + E \\
 &= m\tau + \frac{1}{18} \Delta\psi \cos \epsilon
 \end{aligned}$$

$$g \sin G = B$$

$$g \cos G = nA$$

$$h \sin H = C$$

$$h \cos H = D$$

$$i = C \tan \epsilon$$

$$= -8''.145 \cos \lambda$$

$$f' = \frac{1}{18} d\psi \cos \epsilon$$

$$= mA' \text{ approximately}$$

$$g' \sin G' = B'$$

$$g' \cos G' = nA'$$

where  $m$  and  $n$  are given on page 54.

The quantities  $1 + x$ ,  $1 + y$  and  $\frac{g'}{g_0}$ , which may be termed Cape independent day numbers, are defined by

$$1 + x = \frac{g}{20.0521} = 0.049870 g$$

$$1 + y = \frac{h}{18.50} = 0.054054 h$$

$$\frac{g'}{g_0} = \frac{g'}{20.0521} = 0.0499 g'$$

The Besselian and independent day numbers are used to reduce the right ascension  $\alpha_0$  and declination  $\delta_0$  of a star from the mean equinox of the beginning of the year to the apparent equinox of date. The Besselian day numbers  $A$ ,  $B$  and  $E$  or the independent day numbers  $f$ ,  $g$  and  $G$  yield the reduction for precession and the long-period terms of nutation, while  $C$  and  $D$  or  $h$ ,  $H$  and  $i$  yield the reduction for aberration. The effect of the short-period terms of nutation is given by  $A'$  and  $B'$ , or by  $f'$ ,  $g'$  and  $G'$ .

In addition to the above corrections the mean position of a star must be corrected for proper motion and for parallax (if known and if sensible) in order to obtain the apparent position. In the case of double stars a correction for orbital motion may also be necessary.

The Besselian day numbers are used with Besselian star constants, defined as follows:—

$$\begin{aligned} a &= m^s + n^s \sin \alpha_0 \tan \delta_0 & a' &= n'' \cos \alpha_0 \\ b &= \frac{1}{15} \cos \alpha_0 \tan \delta_0 & b' &= -\sin \alpha_0 \\ c &= \frac{1}{15} \cos \alpha_0 \sec \delta_0 & c' &= \tan \epsilon \cos \delta_0 - \sin \alpha_0 \sin \delta_0 \\ d &= \frac{1}{15} \sin \alpha_0 \sec \delta_0 & d' &= \cos \alpha_0 \sin \delta_0 \end{aligned}$$

Denoting the proper motion by  $\mu$  and supposing the parallax to be negligible, the apparent right ascension  $\alpha$  and declination  $\delta$  are found from

$$\begin{aligned} \alpha &= \alpha_0 + Aa + Bb + Cc + Dd + E + \tau\mu\alpha \\ \delta &= \delta_0 + Aa' + Bb' + Cc' + Dd' + \tau\mu\delta \end{aligned}$$

or

$$\begin{aligned} \alpha &= \alpha_0 + f + \frac{1}{15} g \sin(G + \alpha_0) \tan \delta_0 + \frac{1}{15} h \sin(H + \alpha_0) \sec \delta_0 + \tau\mu\alpha \\ \delta &= \delta_0 + g \cos(G + \alpha_0) + h \cos(H + \alpha_0) \sin \delta_0 + i \cos \delta_0 + \tau\mu\delta \end{aligned}$$

which do not include the effect of short-period terms. Their effect is

$$\begin{aligned} \Delta\alpha &= A'a + B'b = f' + \frac{1}{15} g' \sin(G' + \alpha_0) \tan \delta_0 \\ \Delta\delta &= A'a' + B'b' = g' \cos(G' + \alpha_0) \end{aligned}$$

The short-period terms attain two maxima and two minima during the lunar tropical month. They may amount to  $\pm 0^s.020 \pm 0^s.008 \tan \delta$  in right ascension or  $\pm 0''.13$  in declination.

The formulæ for the use of the Cape independent day numbers are given in Finlay's *Star-Correction Tables*, published as an appendix to *Cape Meridian Observations*, 1890-91. They are not quoted here, as they cannot be used without Finlay's *Tables*.

If several apparent positions of one star are required, or if the Besselian star constants are known with sufficient accuracy, the use of the Besselian day numbers is to be preferred; in other cases the independent day numbers will be found more convenient.

In the case of stars near the poles, if strict accuracy be required, higher order terms must also be included.

The correction for parallax may be written

$$\begin{aligned} \Delta\alpha &= -\frac{1}{15} \pi \sin \alpha \sec \delta X + \frac{1}{15} \pi \cos \alpha \sec \delta Y \\ \Delta\delta &= -\pi \cos \alpha \sin \delta X - \pi \sin \alpha \sin \delta Y + \pi \cos \delta Z \end{aligned}$$

where  $X$ ,  $Y$  and  $Z$  are the Sun's co-ordinates given on pages 30-37.

As an illustration of the application of the above formulæ the apparent position of  $\alpha$  Aquilæ (*Altair*) at upper transit at Greenwich on February 20 will be computed, omitting the short-period terms of nutation, the parallax being  $0''.20$ .

From page 305

$\alpha_0$	<sup>h</sup> 19 <sup>m</sup> 47 <sup>s</sup> 36.680	$\delta_0$	+8° 41' 43.74
Annual var.	+2.9263	Annual var.	+9.462
$\mu_\alpha$	+0.0356	$\mu_\delta$	+0.393

The Besselian star constants  $a$  and  $a'$  are the annual precessions in right ascension and declination respectively, i.e.

$$a = \text{annual variation in R.A.} - \mu_\alpha = +2^s.8907$$

$$a' = \text{annual variation in Dec.} - \mu_\delta = +9''.069$$

The remaining Besselian star constants are

$b$	= +0.0046	$b'$	= +0.892
$c$	= +0.0305	$c'$	= +0.564
$d$	= -0.0601	$d'$	= +0.068

$\alpha_0$		19 <sup>h</sup> .8
Sidereal time at 0 <sup>h</sup> (page 277)		9 <sup>h</sup> .9
Difference = approximate mean time of transit	= 9 <sup>h</sup> .9	= 0 <sup>d</sup> .41

Hence all the variable quantities will be interpolated to February 20.41.

From the formula given above for the correction for parallax, since  $\pi = 0''.20$

$$\Delta\alpha = +0^s.012 X + 0^s.006 Y$$

$$\Delta\delta = -0''.01 X + 0''.03 Y + 0''.20 Z$$

from which, since  $X = +0.86$ ,  $Y = -0.44$ ,  $Z = -0.19$

$$\Delta\alpha = +0^s.010 - 0^s.003 = +0^s.007$$

$$\Delta\delta = -0''.01 - 0''.01 - 0''.04 = -0''.06$$

Using the Besselian day numbers (page 267), and taking  $\tau$  as 0.137 (page 277)

These results may be compared with those on page 494. It must be remembered, however, that values computed by different processes may differ by one or two units of the last decimal. The working units 0<sup>s</sup>.001 and 0<sup>s</sup>.01 are so much smaller than the probable error of a single observation that such small discrepancies are unimportant, provided they are not systematic.

The natural values of the independent day numbers, tabulated on the same pages as the logarithmic values, may also be used with a slide rule, a calculating machine or Crelle's Tables.

When  $g$  or  $i$  is very small it will be found difficult, and in some cases impossible, to interpolate their logarithms. This difficulty may be overcome by interpolating the natural numbers, and, if necessary, taking the logarithm of the interpolated numbers. It will be noted that, when  $i$  is less than about 4",  $\log i$  is given to three decimals only.

The *Sidereal Time* at 0<sup>h</sup>, to the nearest tenth of an hour, is used in determining the interpolating factor for the Besselian or independent day numbers for the time of transit of a star. This factor is

$$\frac{\alpha + \lambda - \text{Greenwich sidereal time at } 0^h}{24}$$

$\lambda$  being here the longitude of the observer.

$\tau$  is the fraction of the tropical year, reckoned from the commencement of the Besselian fictitious year, or 1935.0.

The quantities  $j$  and  $J$  are explained in the following paragraph.

#### *Differential Precession, Nutation and Aberration* (Pages 275-295)

These quantities are intended to facilitate the reduction of observations in which the differences  $\Delta \alpha$  and  $\Delta \delta$  of right ascension and declination of a fixed star and of a moving object are determined. If the position of the star be reduced to the equinox of the beginning of the year (or to that of 1950.0), the right ascension of the moving object, referred to the same equinox, is R.A. of star +  $\Delta \alpha$  + differential aberration + differential precession and nutation, and similarly for the declination.

The differential aberration is independent of the year, or of the equinox to which the observation is being reduced, so that the table given is permanent. A small term  $-0.00004 \cos \lambda \sin \delta \Delta \delta$  has been omitted in the differential aberration in declination. In the case of the differential precession and nutation the values of  $j$  and  $J$  on pages 275-289 are to be used for reductions to the equinox of the beginning of the year, and those on page 294 for reductions to 1950.0.

The quantities tabulated are defined thus:—

$$F(a) = (C \sin a - D \cos a) \sin r^m$$

For reduction to 1935.0

$$j = g \sin r^m = 0.00436 g$$

$$J = G - 6^h$$

For reduction to 1950.0

$$j \sin J_0 = 20.044 (1950 - 1935 - A) \sin r^m$$

$$j \cos J_0 = B \sin r^m = 0.00436 B$$

$$J = J_0 - 1^s.5 (1950 - 1935)$$

Since  $j \cos J_0$  is very small in comparison with  $j \sin J_0$

$$j = j \sin J_0 + \frac{(j \cos J_0)^2}{2j \sin J_0}$$

The small correction to  $J_0$  arises from the fact that the right ascension actually used is that for 1950.0, whereas it is theoretically more accurate to use the value for the epoch mid-way between the time of observation and 1950.0. Assuming an annual precession of  $+3^s.0$ , the small correction above enables the star's right ascension for 1950.0 to be used without sensible error. If  $\Delta \alpha$  or  $\Delta \delta$  is large,  $\alpha$  and  $\delta$  should be replaced by  $\alpha + \frac{1}{2} \Delta \alpha$  and  $\delta + \frac{1}{2} \Delta \delta$ .

The formulæ of application are given on pages 290, 292 and 294, and all the necessary trigonometrical functions on pages 294 and 295.

#### *Mean Places of Stars (Pages 296-307)*

The *Mean Places of Stars* and other data given on these pages are taken from *Positions and Proper Motions of 1504 Standard Stars for the Equinox 1925.0*, by W. S. Eichelberger, in the *Astronomical Papers of the American Ephemeris and Nautical Almanac*, Vol. X, Part I.

The *Magnitudes* have been taken from *Harvard Annals* 50, and are, therefore, the same as those given in the Henry Draper catalogue. In accordance with *Harvard Bulletin* No. 822 the magnitude of  $\gamma$  Argus has been corrected to 1.92.

The *Annual Variations* are the sums of the annual precessions and the annual proper motions.

Stars that lie within  $10^\circ$  of either pole are designated *Circumpolar Stars*, and their mean places are given separately on page 307.

The footnotes give proper names, the range of magnitude of variable stars, and, in the case of double stars, where necessary to guard against mis-identification, the approximate magnitude, distance and position angle of the companion.

#### *Apparent Places of Stars (Pages 308-520)*

The apparent places of 25 circumpolar stars (pages 308-357) are given for every day, and include the effect of short-period terms of nutation. The northern stars are given first, followed by the southern stars. When a star passes the meridian twice in any one mean solar day (as happens once each year) the apparent places

are given for both transits. The values of  $\sec \delta$  and  $\tan \delta$  correspond to the mean place.

The apparent places of stars lying between the limits  $\pm 80^\circ$  of declination (pages 358–520) are given for every tenth transit at Greenwich, and do not include the effect of short-period terms of nutation. For stars whose declination exceeds  $\pm 60^\circ$  only two decimals are given in the right ascension. The mean solar date on which two transits occur is given to the left of the column R.A. The date in the column *Mean Solar Date* is strictly applicable to the middle star on that page, and is rounded to the nearest tenth of a day, except when the fraction lies between .95 and 1.00, when it is rounded to .9, in order to avoid confusion of date. A system of footnotes removes any possibility of ambiguity as to the transit to which the given figures relate. The first differences of each co-ordinate are given, but without signs, the dashes denoting a change of sign.

The six following stars have been corrected for annual parallax.

$\epsilon$ Eridani	0.30	$\alpha$ Centauri	0.76
$\alpha$ Canis Majoris ( <i>Sirius</i> )	0.37	$\alpha$ Aquilæ ( <i>Altair</i> )	0.20
$\alpha$ Canis Minoris ( <i>Procyon</i> )	0.31	$\delta$ Cygni	0.30

The seven following stars have been corrected for the effect of orbital motion, the corrections and the orbits on which they are based being given in Appendix II to Eichelberger's catalogue.

$\alpha$ Canis Majoris ( <i>Sirius</i> )	$\alpha$ Centauri
$\alpha$ Geminorum ( <i>Castor</i> )	$\zeta$ Herculis
$\alpha$ Canis Minoris ( <i>Procyon</i> )	$\delta$ Cygni
$\gamma$ Virginis	

The further corrections required for the effect of short-period terms of nutation are

$$\Delta a = A'a + B'b$$

$$\Delta \delta = A'a' + B'b'$$

for which the Besselian star constants  $a$ ,  $b$ ,  $a'$ ,  $b'$  are given to the degree of accuracy necessary.

The *Authority* is the office in which the calculation of the apparent place has been made. The *Catalogue Number* is the number in Eichelberger's catalogue.

### Eclipses (Pages 521–535)

In computing the eclipses the following corrections have been applied to the tabular positions of the Sun and Moon as given in the *Nautical Almanac*. They correspond to corrections of  $+1''.5$  to the mean longitude as found from Newcomb's *Tables of the Sun*, and of  $+5''.0$  to the mean longitude and  $-0''.5$  to the latitude as found from Brown's *Tables of the Moon*. They are assumed to be constant during the eclipse.

*Eclipses of the Sun.* The particulars given under *Elements of the Eclipse* are for the moment of conjunction of the Sun and Moon in right ascension, and not for the time of New Moon, which is the moment of conjunction of the Sun and Moon in longitude.

The Sun's true semi-diameter is based on a value at unit distance of  $959''.63$  as given by Auwers in *Astronomische Nachrichten*, 3046, 367. The semi-diameter used for the Sun's ephemeris elsewhere in the *Nautical Almanac* is based on a value of  $961''.18$  at unit distance; the difference represents the allowance for irradiation, the effects of which must be removed for eclipse purposes.

The Moon's true semi-diameter is based on a value  $0.272274$  of  $k$ , the ratio of the Moon's equatorial radius to that of the Earth; the value used for the semi-diameter in the Moon's ephemeris is  $0.272481$ .

The *Besselian Elements of the Eclipse* are given to facilitate the accurate computation of the circumstances of the eclipse for any place on the Earth's surface. Their geometrical significance is as follows.

The fundamental plane passes through the centre of the Earth and is at right angles to the axis of the Moon's shadow, i.e. to the line joining the centres of the Sun and Moon. The position of a point may be defined by a system of rectangular axes with origin at the centre of the Earth. The  $x$  axis is the intersection of the equator and the fundamental plane and is directed positively towards the east as seen from the Moon; the  $y$  axis is perpendicular to that of  $x$  and is directed positively towards the north; the  $z$  axis is parallel to the axis of the shadow and is positive towards the Moon. The unit of measurement adopted for these co-ordinates is the Earth's equatorial radius.

The radius of the shadow cone on the fundamental plane is denoted by  $l$ , and  $x$  and  $y$  are the co-ordinates of the centre of the shadow,  $\alpha$ ,  $\gamma$  and  $z$  being the co-ordinates of the centre of the Moon. The direction of the shadow is defined by  $\mu$  and  $d$ , which are the Greenwich hour angle and the declination of the point  $Z$  on the celestial sphere towards which the axis of the shadow is directed. The values of  $x$ ,  $y$ ,  $l$ ,  $\sin d$ ,  $\cos d$  and  $\mu$  are tabulated for every 10 minutes during the eclipse.  $\tan f$ , where  $f$  is the angle that the boundary of the shadow cone makes with the axis of the shadow, is constant throughout the eclipse.

The formulæ for determining these quantities are as follows. Let  $\alpha_\epsilon$ ,  $\delta_\epsilon$ ,  $r$  and  $\alpha_0$ ,  $\delta_0$ ,  $R$  be the right ascension, declination and distance from the centre of the Earth of the centres of the Moon and Sun respectively, and let  $b = \frac{\sin \pi_0}{\sin \pi_\epsilon}$  where  $\pi_0$  and  $\pi_\epsilon$  are the Sun's and Moon's equatorial horizontal parallaxes. Then  $a$  and  $d$ , the right ascension and declination of the point  $Z$ , are given by

$$a = \alpha_0 - \frac{b}{1-b} \cos \delta_\epsilon \sec \delta_0 (\alpha_\epsilon - \alpha_0)$$

$$d = \delta_0 - \frac{b}{1-b} (\delta_\epsilon - \delta_0)$$

Whence

$$\mu = \text{Greenwich sidereal time} - a$$

$$x = r \cos \delta_\epsilon \sin(\alpha_\epsilon - a)$$

$$y = r [\sin \delta_\epsilon \cos d - \cos \delta_\epsilon \sin d \cos(\alpha_\epsilon - a)]$$

$$z = r [\sin \delta_\epsilon \sin d + \cos \delta_\epsilon \cos d \cos(\alpha_\epsilon - a)]$$

$$\text{where } r = \frac{1}{\sin \pi_\epsilon}$$

For the penumbral cone

$$\tan f_1 = \frac{0.00466407}{R(1-b)} \quad l_1 = z \tan f_1 + 0.272277$$

and for the umbral cone

$$\tan f_2 = \frac{0.00464083}{R(1-b)} \quad l_2 = z \tan f_2 - 0.272277$$

The *Circumstances of the Eclipse* are, in the case of partial eclipses, the times, for the Earth generally, of beginning, greatest phase and end, together with the latitudes and longitudes of the places on the Earth at which these phases occur. In the case of total and annular eclipses, the same data are given for the beginning and end of central eclipse; also the time and place at which central eclipse occurs at local apparent noon, or, when the eclipse occurs on the side of the elevated pole remote from the Sun, the time and place at which central eclipse occurs at local apparent midnight.

The eclipse maps show the localities where the eclipses are visible and enable the times of beginning and end for any place to be approximately obtained.

*Local Predictions.* The times of beginning and end of the eclipse for a given observer are determined by the fact that at these moments the distance of the observer from the axis of the penumbra will be equal to the radius of the shadow cone on a plane through the point of observation and parallel to the fundamental plane. The procedure adopted is to compute the co-ordinates  $\xi$ ,  $\eta$  and  $\zeta$  of the observer, together with their variations, for some assumed moment near the time of the phase required. The co-ordinates  $x$  and  $y$  of the centre of the shadow, and their variations, are determined from the values tabulated. From these two sets of co-ordinates the distance and direction of the observer from the centre of the shadow are obtained, together with their variations. The radius of the penumbra at the distance  $\zeta$  above the fundamental plane is also calculated, and by the use of the computed values of the several variations the correction to the assumed time to give the true time of the phase concerned is obtained.

The formulæ are as follows:—

$$\begin{aligned} \xi &= \rho \cos \phi' \sin(\mu - \lambda) \\ \eta &= \rho \sin \phi' \cos d - \rho \cos \phi' \sin d \cos(\mu - \lambda) \\ \zeta &= \rho \sin \phi' \sin d + \rho \cos \phi' \cos d \cos(\mu - \lambda) \end{aligned}$$

where  $\rho \sin \phi'$  and  $\rho \cos \phi'$  are the geocentric co-ordinates of the place of observation (see pages 726-727) and  $\lambda$  is its longitude.

The variations per minute are

$$\begin{aligned} \xi' &= \{0.0043635 + 0.0000012(10 - \Delta\alpha_0)\} \rho \cos \phi' \cos(\mu - \lambda) \\ \eta' &= \{0.0043635 + 0.0000012(10 - \Delta\alpha_0)\} \xi \sin d \end{aligned}$$

where  $\Delta\alpha_0$  is the Sun's hourly motion, in seconds of time, as given in the elements of the eclipse. Since  $\Delta\alpha_0$  and  $\sin d$  may here be regarded as constant throughout the eclipse, the numerical values of the coefficients in  $\xi'$  and  $\eta'$  are given at the foot of the Besselian elements. The variations per minute of  $x$  and  $y$ , denoted by  $x'$  and  $y'$ , are obtained by dividing the differences between successive tabular values of  $x$  and  $y$  by 10.

The distance  $m$  and position angle  $M$  of the axis of the shadow relative to the observer may be determined from

$$\begin{aligned} m \sin M &= x - \xi \\ m \cos M &= y - \eta \end{aligned}$$

The magnitude  $n$  and direction  $N$  of the motion of the centre of the shadow relative to the observer are found from

$$\begin{aligned}n \sin N &= x' - \xi' \\n \cos N &= y' - \eta'\end{aligned}$$

The radius  $L$  at a distance  $\xi$  above the fundamental plane is

$$L = l - \xi \tan f$$

When the eclipse is beginning or ending  $m = L_1$ , and when the annular or the total phase is beginning or ending  $m = L_2$ .

The correction  $\tau$  to the assumed time may be computed from

$$\tau = - \frac{m \cos(M - N)}{n} + \frac{L \cos \psi}{n}$$

where 
$$\sin \psi = \frac{m \sin(M - N)}{L}$$

The value of  $\psi$  for which  $\cos \psi$  is negative should be taken for the beginning of the eclipse, for the beginning of the annular phase or the end of the total phase, and the value for which  $\cos \psi$  is positive for the end of the eclipse, for the end of the annular phase or the beginning of the total phase. If the correction  $\tau$  exceeds two or three minutes, and great accuracy is desired, a repetition of the computation should be made, using the adjusted times in place of those originally assumed.

The time of greatest eclipse or the middle of the eclipse is the moment when the value of  $m$  is a minimum, and is not necessarily the time midway between the beginning and the end. If a time is assumed for this phase the correction is given by

$$\tau = - \frac{m \cos(M - N)}{n}$$

The magnitude of greatest eclipse is the fraction of the Sun's diameter that is obscured by the Moon at mid-eclipse, measured along the line joining the centres of the two discs, and is given by

$$\frac{L_1 - \Delta}{2L_1 - 0.5459}$$

where  $\Delta = m \sin(M - N)$  and is always to be taken positively.

The position angle of the point of contact, measured from the north point of the Sun's limb in the direction N.E.S.W., may be obtained from

$$P = N + \psi$$

or, if reckoned from the vertex, from

$$V = P - C$$

where  $C$ , the parallactic angle, is given by  $\tan C = \frac{\xi}{\eta}$ .

An alternative method of computing the time of beginning or end of an eclipse consists in finding values of  $m$  at convenient intervals—10<sup>m</sup> or 1<sup>m</sup>—near the time of the phase required, from

$$m^2 = (x - \xi)^2 + (y - \eta)^2$$

and then determining when  $L - m = 0$ . The position angle of the point of contact is found by interpolating  $x - \xi$  and  $y - \eta$  to the time of contact, and finding  $M$ , since at this moment  $M = P$ .

The middle of an eclipse may be determined by finding  $x_1 - \xi_1$  and  $y_1 - \eta_1$  for a time before the middle, and  $x_2 - \xi_2$  and  $y_2 - \eta_2$  for a time after the middle. The middle is then at the vanishing point of

$$(x - \xi)\{(x_2 - \xi_2) - (x_1 - \xi_1)\} + (y - \eta)\{(y_2 - \eta_2) - (y_1 - \eta_1)\}$$

which is computed for the two times, and which is negative before the middle and positive afterwards. To determine the magnitude of greatest eclipse,  $L_1$ ,  $x - \xi$  and  $y - \eta$  are interpolated to the time of the middle, and  $m$  is found. The magnitude is then

$$\frac{L_1 - m}{2L_1 - 0.5459}$$

If great accuracy is required, the two chosen times should not be more than one minute apart.

The angle  $M$  is, at all times, the position angle of the centre of the Moon referred to the centre of the Sun, or the direction of greatest obscuration, the direction of greatest illumination being  $M \pm 180^\circ$ . The apparent semi-diameter of the Sun, as adopted for eclipse purposes, is

$$\text{Sun's semi-diameter} = \frac{959''.63}{R}$$

The apparent semi-diameter of the Moon, including the effect of augmentation, is

$$\frac{L_1 - L_2}{L_1 + L_2} \times \text{Sun's semi-diameter}$$

The apparent distance of the Moon's centre from that of the Sun is

$$\frac{2m}{L_1 + L_2} \times \text{Sun's semi-diameter}$$

The maximum angular breadth of the obscured portion of the Sun is

$$\frac{2(L_1 - m)}{L_1 + L_2} \times \text{Sun's semi-diameter}$$

The maximum angular breadth of the illuminated portion is

$$\frac{2(L_2 + m)}{L_1 + L_2} \times \text{Sun's semi-diameter}$$

The position angles of the cusps, reckoned from the north point of the Sun through the east in the usual way, are  $M \pm A$ , where

$$\tan^2 \frac{A}{2} = \frac{(L_1 - m)(m - L_2)}{(L_1 + m)(m + L_2)}$$

The position angles of the cusps, reckoned from the north point of the Moon, are  $M \pm 180^\circ \pm B$ , where

$$\tan^2 \frac{B}{2} = \frac{(L_1 - m)(m + L_2)}{(L_1 + m)(m - L_2)}$$

Note that

$$\frac{\sin A}{\sin B} = \frac{L_1 - L_2}{L_1 + L_2} = \frac{\text{Moon's semi-diameter}}{\text{Sun's semi-diameter}}$$

The "overhang" of the Moon, measured along the Sun's radius, at a point  $r^\circ$  distant from the cusp, as measured along the Moon's limb, is

$$\frac{2m \sin r^\circ \sin A}{L_1 + L_2} \times \text{Sun's semi-diameter}$$

$$= \frac{2m \sin r^\circ \sin B}{L_1 + L_2} \times \text{Moon's semi-diameter}$$

The angular distance, measured in degrees along the Moon's limb, from either cusp to the point where the Moon forms an imaginary cusp with a stratum of the Sun's atmosphere  $S$  seconds of arc above the adopted semi-diameter, is

$$\frac{S (L_1 + L_2)}{2 \sin r^\circ m \sin A \times \text{Sun's S.D.}} = \frac{0.02985 RS (L_1 + L_2)}{m \sin A}$$

This formula, which is a differential one, must not be used if the resulting angular distance is more than  $3^\circ$  or  $4^\circ$ .

In the preparation of diagrams illustrating the appearance of the illuminated portion of the Sun at any moment, the Sun's semi-diameter may be regarded as unity in the above formulæ. Also it will suffice to put  $L_2 = L_1 - 0.5459$ .

The altitude of the Sun and the parallactic angle  $C$  may be computed from

$$\sin \text{altitude} = \sin \phi \sin d + \cos \phi \cos d \cos(\mu - \lambda)$$

$$\sin C = \cos \phi \sin(\mu - \lambda) \sec \text{altitude}$$

in which  $\cos C$  has the same sign as  $\eta$ . In cases where a possible error of  $0.2$  in these quantities would be considered negligible, it suffices to use

$$\sin \text{altitude} = \zeta \qquad \tan C = \frac{\xi}{\eta}$$

The rigorous determination of the shape and position of the Moon's shadow on the Earth at any given moment must be made by text-book methods. A good approximation is obtained by regarding the outline of the shadow as an ellipse, centred at that point on the central line at which mid-eclipse occurs at the given moment, having its major axis directed towards the Sun, and having semi-major and semi-minor axes, in miles, of  $3963 L_2 \operatorname{cosec}(\text{Sun's altitude})$  and  $3963 L_2$  respectively.

*Example of Local Prediction.* The circumstances of the partial eclipse of February 3 will be computed for Montreal, for which we find, from pages 690-691,  $\lambda = +73^\circ 34' 7''$ ,  $\rho \sin \phi' + 0.70974$ ,  $\rho \cos \phi' = +0.70205$ . If approximate times and angles only are required, it suffices to use a simple 3-figure calculation as follows, in which  $\sin d$  and  $\cos d$  have the fixed values  $-0.287$  and  $+0.958$ .

G.M.T.	15 <sup>h</sup>	16 <sup>h</sup>	17 <sup>h</sup>	18 <sup>h</sup>

## EXPLANATION, 1935

These values of  $x - \xi$  and  $y - \eta$  are now plotted on any convenient scale, e.g. 1 unit = 10 inches, or 5 inches, or 10 centimetres, remembering that the positive direction of  $x - \xi$  is to the east, and of  $y - \eta$  to the north. The value of  $L_1$  may be assumed to be  $L_1 = 0.003$ , the latter term being the average value of  $\xi \tan f$ ; the maximum value is 0.005. A circle of radius  $L_1$  is drawn with centre at the origin. The plotted points are joined by straight lines, cutting the circle at B and E. OM is drawn perpendicular to the plotted line. The times corresponding to B, M and E represent the beginning, middle and end of the eclipse, while the position angles of the points of first and last contact are the angles NOB and NOE, measured through the east in the usual way. The distance OM =  $\Delta$ . Measurement of the accompanying diagram gives

	G.M.T.	$P$
Beginning	15 33	274
Middle	16 36	329
End	17 39	24

Magnitude 0.45

The angle shown under  $P$  for the middle of the eclipse is the direction OM, i.e. the direction of the Moon, or of greatest obscuration.

More accurate results can be obtained by a 4-figure calculation, as shown. The times chosen for this calculation, which are at intervals of 10<sup>m</sup> (to avoid interpolation of  $x$ ,  $y$  and  $\mu$ ) may be found from the map on page 525, or from the previous calculation.

$L_1$			+0.5355			
$m$			+0.2966			
$L_1 - m$			+0.2389			
$2L_1 - 0.5459$			+0.5251			
Magnitude			0.455			

The discriminant is  $L_1 - m$  for the beginning and end of the eclipse, and

$$(\pi - \xi)\{(\pi_2 - \xi_2) - (\pi_1 - \xi_1)\} + (\gamma - \eta)\{(\gamma_2 - \eta_2) - (\gamma_1 - \eta_1)\}$$

for the middle.

If still further accuracy were required in the case of the first and last contacts, similar 5-figure calculations would be made, using as initial times 15<sup>h</sup> 33<sup>m</sup>, 15<sup>h</sup> 34<sup>m</sup>, 17<sup>h</sup> 39<sup>m</sup> and 17<sup>h</sup> 40<sup>m</sup>.

To prepare a diagram showing the appearance of the Sun as seen by the naked eye at any moment, say at the middle of the eclipse, a circle of unit radius is first

drawn to represent the Sun. The centre of the Moon is in position angle  $M - C$ , here  $335^\circ$ , reckoned from the vertex in the direction N.E.S.W., and its distance is

$$\frac{m}{L_1 - 0.273} = \frac{0.297}{0.263} = 1.13$$

The radius of the Moon is

$$\frac{0.273}{L_1 - 0.273} = \frac{0.273}{0.263} = 1.04$$

The complete drawing, as shown in the accompanying illustration, can now be made.

The position angles of the cusps, reckoned from the north point of the Sun, are given by  $M \pm A$ , where

$$\begin{aligned} \tan^2 \frac{A}{2} &= \frac{(L_1 - m)(m + 0.5459 - L_1)}{(L_1 + m)(m + L_1 - 0.5459)} \\ &= \frac{0.2389 \times 0.3070}{0.8321 \times 0.2862} = 0.3080 \end{aligned}$$

whence  $A = 58^\circ.1$  and the required position angles are  $328^\circ.9 \pm 58^\circ.1 = 27^\circ.0$  and  $270^\circ.8$ . The position angles from the vertex are  $335^\circ.2 \pm 58^\circ.1 = 33^\circ.3$  and  $277^\circ.1$ .

*Corrections to the Besselian Elements.* It is sometimes desirable to introduce corrections to the Besselian elements, depending on revised values of the corrections  $\Delta\lambda_0$  and  $\Delta\lambda_1$  to the *mean* longitudes of the Sun and Moon. The corrections are first converted to corrections to the right ascension and declination as follows.

$$\begin{aligned}\Delta\alpha_0 &= 0.000282 \Delta\lambda_0 \times \text{variation per day of Sun's R.A.} \\ \Delta\delta_0 &= 0.000282 \Delta\lambda_0 \times \text{variation per day of Sun's Dec.} \\ \Delta\alpha_1 &= 0.000506 \Delta\lambda_1 \times \text{variation per hour of Moon's R.A.} \\ \Delta\delta_1 &= 0.000506 \Delta\lambda_1 \times \text{variation per hour of Moon's Dec.}\end{aligned}$$

If  $\Delta\lambda_0$  and  $\Delta\lambda_1$  are in seconds of arc, these corrections will be in the same units as the corresponding variations. Corrections to the *true* longitude and latitude would be converted to corrections to the right ascension and declination by

$$\begin{aligned}\cos \delta \Delta\alpha &= \cos S \cos \beta \Delta\lambda - \sin S \Delta\beta \\ \Delta\delta &= \sin S \cos \beta \Delta\lambda + \cos S \Delta\beta\end{aligned}$$

where  $\sin S = \cos \lambda \sec \delta \sin \epsilon = \cos \alpha \sec \beta \sin \epsilon$ , and  $S$  lies between  $\pm 90^\circ$ . The only elements that require alteration are  $x$  and  $y$ , to which the corrections to be applied are

$$\begin{aligned}\Delta x &= \frac{15 \cos \delta_1 (\Delta\alpha_1 - \Delta\alpha_0)}{\pi_1} \\ \Delta y &= \frac{\Delta\delta_1 - \Delta\delta_0}{\pi_1}\end{aligned}$$

*Eclipses of the Moon.* The *Elements and Circumstances of the Eclipse* are similar to those described for solar eclipses. The times and similar circumstances of a lunar eclipse are, of course, the same for all parts of the Earth. The times of contact are derived as follows.

Let  $\alpha, \delta$  be the right ascension and declination of the Moon  $M$ , and  $\alpha', \delta'$  the right ascension and declination of that point  $S$  towards which the centre of the Earth's shadow is directed ( $\alpha' = \text{R.A. of Sun} + 12^h$ ,  $\delta' = -\text{Sun's declination}$ ).

Let  $L$  be the angle between the centres of the Moon and the shadow. Then in the spherical triangle formed by joining the points  $M, S$  and the north pole  $P$

$$\begin{aligned}\sin L \sin Q &= \cos \delta \sin(\alpha - \alpha') \\ \sin L \cos Q &= \sin \delta \cos \delta' - \cos \delta \sin \delta' \cos(\alpha - \alpha')\end{aligned}$$

where  $Q$  is the angle  $PSM$ . The problem consists of finding the times at which these equations are satisfied when the appropriate values of  $L$  (see below) are substituted in them. The equations can with sufficient accuracy be reduced to

$$\begin{aligned}L \sin Q &= (\alpha - \alpha') \cos \delta \\ L \cos Q &= \delta - \delta' + \epsilon\end{aligned}$$

where  $\epsilon = \frac{\sin 2\delta \sin^2 \frac{1}{2}(\alpha - \alpha')}{\sin 1''}$  and can usually be ignored.

Let  $\pi, s$  = parallax and semi-diameter of the Moon

$\pi', s'$  = parallax and semi-diameter of the Sun.

The shadow will differ somewhat from a cone as the Earth is not a true sphere, but it will suffice to use a mean radius for the Earth, which is equivalent to substituting for  $\pi$  a parallax  $\pi_1$ , reduced to latitude  $45^\circ$ , so that  $\pi_1 = 0.9983 \pi$ .

Moreover, observation has shown that the Earth's atmosphere has the effect of increasing the apparent breadth of the shadow by about one-fiftieth. Hence the values of  $L$  to be substituted in the above equations will be, for first and last contacts with the penumbra

$$L = 1.02 (\pi_1 + s' + \pi') + s$$

for first and last contacts with the umbra

$$L = 1.02 (\pi_1 - s' + \pi') + s$$

and for second and third contacts with the umbra (the beginning and ending of totality)

$$L = 1.02 (\pi_1 - s' + \pi') - s$$

To solve the equations a method similar to that adopted for solar eclipses is used.

$$\begin{array}{ll} \text{Let } x = (a - a') \cos \delta & x' = \text{hourly variation of } x \\ y = \delta - \delta' + \epsilon & y' = \text{hourly variation of } y \end{array}$$

$x$  and  $y$  are computed for several successive hours at the time of eclipse,  $x'$  and  $y'$  are found from their differences, and if  $x_0$  and  $y_0$  be the values of  $x$  and  $y$  at some moment  $T_0$  near opposition, then for any particular time of contact  $T$

$$\begin{array}{l} L \sin Q = x_0 + x' (T - T_0) \\ L \cos Q = y_0 + y' (T - T_0) \end{array}$$

Putting

$$\begin{array}{ll} m \sin M = x_0 & n \sin N = x' \\ m \cos M = y_0 & n \cos N = y' \end{array}$$

then

$$\sin \psi = \frac{m \sin(M - N)}{L}$$

and

$$T - T_0 = - \frac{m \cos(M - N)}{n} + \frac{L \cos \psi}{n}$$

$\cos \psi$  being taken with the negative sign for first contact and with the positive sign for last contact. If desired the computations may be repeated, using the times just obtained as initial times.

The time of greatest obscuration, or the middle of the eclipse, is given by

$$T_0 - \frac{m \cos(M - N)}{n}$$

The magnitude of the eclipse, the Moon's diameter being unity, is  $\frac{L - \Delta}{2s}$ ,

where  $\Delta = m \sin(M - N)$ , taken positively for the time of mid-eclipse, the value of  $L$  being the mean of those used for the first and last umbral contacts.

The position angle of contact on the Moon's limb, measured from the north point in the direction N.E.S.W., is  $180^\circ + N + \psi$ .

The latitudes and longitudes of the places that have the Moon in the zenith at first and last umbral contacts are determined by

$$\begin{array}{l} \lambda = \text{Greenwich sidereal time} - \alpha \\ \phi = \delta \end{array}$$

For further details of eclipse prediction reference may be made to Chauvenet's *Manual of Spherical and Practical Astronomy*, to Buchanan's *Mathematical Theory of Eclipses*, and to the *Monthly Notices of the Royal Astronomical Society*, 87, 483, and 93, 175, 414 and 536.

### *Lunar Occultations (Pages 536-563)*

The information concerning lunar occultations consists of the mean places of occultation stars (pages 536-537), reductions from mean place to apparent place (pages 538-541), elements of occultations (pages 542-555) and predictions of occultations visible at Greenwich, Edinburgh, Cape of Good Hope and Johannesburg (pages 556-563). As occultations are now used, not for the determination of longitude, but for the accurate determination of the Moon's position, elements are not given in cases where the occultation could not be observed from any fixed observatory under satisfactory conditions. They are not given within 48 hours of New Moon. Stars fainter than magnitude 5.5 are not included for 48 hours before and after Full Moon, and stars fainter than magnitude 4.5 are excluded for 24 hours before and after Full Moon. In the computation of the elements a correction of  $+5''.0$  has been applied to the mean longitude of the Moon.

The list given in the *Mean Places of Occultation Stars* includes all stars of magnitude 6.5 or brighter contained in the Washington Zodiacal Catalogue (Hedrick), *Astronomical Papers of the American Ephemeris and Nautical Almanac*, Vol. VIII, Part III, that are occulted during the year, except stars whose mean places are given on pages 296-307.

The *Reductions of Occultation Stars* are the quantities to be added to the mean places of the stars in order to obtain the apparent places for the time of occultation. The numbers correspond to the numbers in the elements.

The *Elements of Occultations* furnish the means whereby the times and circumstances of occultations of stars or planets by the Moon may be predicted for any locality on the Earth. The *Limiting Parallels* are the extreme limits of latitude, north and south, between which the path of the Moon's shadow across the Earth will lie. Owing to the varying inclination of the shadow path to the equator it does not follow that an occultation will necessarily be visible even if the observer is situated within these limits.

The Besselian elements of the occultation for the moment of geocentric conjunction of the star and Moon in right ascension are similar to those already described for solar eclipses. In occultations the fundamental plane passes through the centre of the Earth and is at right angles to the line joining the star and the centre of the Moon. Owing to the distance of the star the Moon's shadow becomes a cylinder whose intersection with the fundamental plane is a circle of invariable size, its diameter being equal to that of the Moon. The value used in occultations for the ratio  $k$  of the Moon's radius to the Earth's equatorial radius is 0.2725. This value is somewhat larger than that used for eclipses because the eclipse diameter is based on the disappearance of the last Baily's bead, and therefore represents the diameter between the lowest portions of the lunar valleys, whilst an occultation of a star can take place at any point between the summit of a lunar mountain and the lower portion of a lunar valley.

The formulæ for  $x$  and  $y$ , the co-ordinates of the centre of the shadow on the fundamental plane, are

$$x = \frac{\cos \delta_{\epsilon} \sin(\alpha_{\epsilon} - \alpha_{*})}{\sin \pi}$$

$$y = \frac{\sin \delta_{\epsilon} \cos \delta_{*} - \cos \delta_{\epsilon} \sin \delta_{*} \cos(\alpha_{\epsilon} - \alpha_{*})}{\sin \pi}$$

where  $\pi$  is the Moon's horizontal parallax. These may be reduced, with sufficient accuracy, to

$$x = \frac{15 \cos \delta_{\epsilon} (\alpha_{\epsilon} - \alpha_{*})}{\pi} \quad y = \frac{\delta_{\epsilon} - \delta_{*}}{\pi}$$

where  $\alpha_{\epsilon} - \alpha_{*}$  is in seconds of time, and  $\delta_{\epsilon} - \delta_{*}$  and  $\pi$  are in seconds of arc.

At the moment of conjunction of the star and Moon in right ascension the co-ordinate  $x$  will be zero and the Besselian elements tabulated are

$T_0$  = Greenwich mean time of conjunction

$H$  = Greenwich hour angle of the star at that moment, reckoned positively towards the west and negatively towards the east

$Y$  = value of the co-ordinate  $y$  at the moment of conjunction

$x', y'$  = variations of  $x$  and  $y$  in one hour of mean time.

The value of  $T_0$  is obtained by inverse interpolation in the Moon's hourly ephemeris to obtain the moment when the right ascension of the Moon is equal to that of the star.  $H$  is derived from

$$H = \text{Greenwich sidereal time of conjunction} - \alpha$$

where  $\alpha$  is the common right ascension of the star and Moon.

At the present time the observed mean longitude of the Moon is in excess of the tabular mean longitude by about  $5''$ , and to correct for this the values of  $T_0$  and  $H$  as derived from the Moon's ephemeris are adjusted by the addition of  $-0^m.15$ .

The values of  $x'$  and  $y'$  are derived from

$$x' = \frac{15 \cos \delta_{\epsilon} \Delta \alpha_{\epsilon}}{\pi} \quad y' = \frac{\Delta \delta_{\epsilon}}{\pi}$$

where  $\Delta \alpha_{\epsilon}$  and  $\Delta \delta_{\epsilon}$  are the variations per hour of the Moon's right ascension and declination.

An alternative method of calculating the above elements consists in computing  $x$  and  $y$  for the integral hour  $T_1$  before and the integral hour  $T_2$  after conjunction, thus avoiding interpolation of  $\alpha_{\epsilon}$  and  $\delta_{\epsilon}$ . Calling these  $x_1, y_1$  and  $x_2, y_2$

$$x' = x_2 - x_1 \quad y' = y_2 - y_1$$

$$T_0 = T_1 - \frac{x_1}{x'} - 0^m.15$$

$$Y = y_1 - \frac{x_1}{x'} y'$$

$$H = \text{sidereal time at } 0^h + \text{sidereal equivalent of } T_0 - \alpha_{*}$$

The limiting parallels  $\phi_1$  and  $\phi_2$  are derived from the following formulæ\*, in which the declination of the star is denoted by  $\delta$ .

$$\begin{aligned}\tan N &= \frac{x'}{y'} & (N \text{ less than } 90^\circ) \\ \cos \gamma_1 &= Y \sin N + 0.2725 & (\gamma_1 \text{ less than } 180^\circ) \\ \cos \gamma_2 &= Y \sin N - 0.2725 & (\gamma_2 \text{ less than } 180^\circ) \\ \sin \beta &= \sin N \cos \delta & (\beta \text{ less than } 90^\circ)\end{aligned}$$

Then, for northern declinations

- |  |  |
|--|--|
| (1) If $\cos \gamma_2$ is greater than $\sin \beta$  | $\phi_1 = \beta + \gamma_2$                    |
| (2) If $\cos \gamma_2$ is less than $\sin \beta$ and |  |
| (a) $\gamma_1$ is imaginary                          | $\phi_1 = +90^\circ$                           |
| (b) $\cos \gamma_1$ is greater than $\sin \beta$     | $\phi_1 = +90^\circ$                           |
| (c) $\cos \gamma_1$ is less than $\sin \beta$        | $\phi_1 = 180^\circ - \beta - \gamma_1$        |
| (3) If $\cos \gamma_2$ is greater than $-\sin N$     | $\sin \phi_2 = \sin(N - \gamma_2) \cos \delta$ |
| (4) If $\cos \gamma_2$ is less than $-\sin N$        | $\phi_2 = -(90^\circ - \delta)$                |
| (5) If $\gamma_2$ is imaginary and                   |  |
| (a) $\cos \gamma_1$ is greater than $-\sin N$        | $\phi_2 = -(90^\circ - \delta)$                |
| (b) $\cos \gamma_1$ is less than $-\sin N$           | $\sin \phi_2 = \sin(N - \gamma_1) \cos \delta$ |

For southern declinations

- |  |  |
|--|--|
| (1) If $\cos \gamma_1$ is less than $-\sin \beta$        | $\phi_2 = \gamma_1 - \beta - 180^\circ$        |
| (2) If $\cos \gamma_1$ is greater than $-\sin \beta$ and |  |
| (a) $\gamma_2$ is imaginary                              | $\phi_2 = -90^\circ$                           |
| (b) $\cos \gamma_2$ is less than $-\sin \beta$           | $\phi_2 = -90^\circ$                           |
| (c) $\cos \gamma_2$ is greater than $-\sin \beta$        | $\phi_2 = \beta - \gamma_2$                    |
| (3) If $\cos \gamma_1$ is less than $\sin N$             | $\sin \phi_1 = \sin(N + \gamma_1) \cos \delta$ |
| (4) If $\cos \gamma_1$ is greater than $\sin N$          | $\phi_1 = 90^\circ + \delta$                   |
| (5) If $\gamma_1$ is imaginary and                       |  |
| (a) $\cos \gamma_2$ is less than $\sin N$                | $\phi_1 = 90^\circ + \delta$                   |
| (b) $\cos \gamma_2$ is greater than $\sin N$             | $\sin \phi_1 = \sin(N + \gamma_2) \cos \delta$ |

*Predictions of Occultations* visible at Greenwich, Edinburgh, Cape of Good Hope and Johannesburg are given on pages 556-563, while, by means of the longitude and latitude coefficients  $a$  and  $b$ , the times given may be adjusted for neighbouring observatories.

Predictions for a number of stars in addition to those whose Besselian elements are given on pages 542-555 are included, the supplementary list comprising, *inter alia*, the remainder of the fainter stars in the Washington Zodiacal Catalogue (Hedrick).

The following limitations have been imposed:—

- (1) The star is at least  $10^\circ$  above the horizon at the time given.
- (2) Except for bright stars and planets no occultations are given that would occur in daylight or bright twilight.
- (3) In the case of stars fainter than magnitude 6.5 a progressive restriction, depending upon the magnitude of the star, has been imposed during the period from one day before last quarter to one day after first quarter, to which period the predictions for these stars are limited.

---

\*These formulæ replace those of Chauvenet, which are very incompletely stated.

- (4) Bright limb phenomena are given only in the case of stars of magnitude 3.5 or brighter for reappearances, and of magnitude 4.5 or brighter for disappearances.

The approximate time of occultation at a place  $\Delta\lambda$  degrees west and  $\Delta\phi$  degrees north of one of the stations for which particulars are given may be obtained from

$$\text{Approximate time} = \text{predicted G.M.T.} + a \Delta\lambda + b \Delta\phi$$

For example. if the time of occultation of 17 Tauri on January 14 is required for Stonyhurst College Observatory it may be obtained from the predicted particulars for either Edinburgh or Greenwich.

	From Edinburgh		From Greenwich	
	$\Delta\lambda = -0^{\circ}.7$		$\Delta\lambda = +2^{\circ}.5$	
	$\Delta\phi = -2^{\circ}.1$		$\Delta\phi = +2^{\circ}.4$	
Predicted G.M.T. ...	<sup>h</sup> 16	<sup>m</sup> 58	<sup>h</sup> 16	<sup>m</sup> 50
$a \Delta\lambda$ ...	+	0.3	-	1.5
$b \Delta\phi$ ...	-	4.6	+	4.6
G.M.T. at Stonyhurst	16	53.5	16	53

The particulars for the nearer station will usually be used, but the mean of the times obtained from both stations may be employed in the case of places situated in the Midlands or Northern England.

For distances up to 300 miles the error of this formula will not, in general, exceed 2<sup>m</sup>. In the case of grazing or brief occultations where linear variations cannot be used with safety, the coefficients have been omitted. The times are given to the nearest half minute only. The column headed  $P$  gives the position angle of the star at the time given, measured from the north point of the Moon in the direction N.E.S.W.

The formulæ used in the predictions are similar to those for solar eclipses. The co-ordinates on the fundamental plane of the centre of the shadow are denoted by  $x$  and  $y$  and those of the observer by  $\xi$  and  $\eta$ . When the distance between the observer and the centre of the shadow is equal to  $k$  an occultation will be beginning or ending. This leads to the fundamental equation

$$(x - \xi)^2 + (y - \eta)^2 = k^2$$

which has two real roots (or none) corresponding to immersion and emersion.

The predictions of occultations for Greenwich and Edinburgh form part of a general scheme of prediction for eight stations,\* which with the  $a$  and  $b$  coefficients cover the greater part of northern and western Europe. Preliminary times are obtained for four of these stations by an adaptation of the principles involved in the graphical method of Father Rigge,† and after these times have been corrected preliminary times for the remaining stations are obtained by means of the  $a$  and  $b$  coefficients. The preliminary times are corrected differentially as follows.

\* The other stations are Paris (published in the *Connaissance des Temps*), Berlin, Munich and Königsberg (published in the *Berliner Jahrbuch*), Brussels (published in *Annuaire de l'Observatoire Royal de Belgique*), and Copenhagen (published in *Nordisk Astronomisk Tidsskrift*).

† *The Graphic Construction of Eclipses and Occultations*, Loyola University Press, Chicago, 1924.

Let  $T$  = preliminary time  
 $T_0$  = time of conjunction  
 $t = T - T_0$

whence  $x = x't \quad y = Y + y't$   
 $\xi = \rho \cos \phi' \sin h$   
 $\eta = \rho \sin \phi' \cos \delta - \rho \cos \phi' \cos h \sin \delta = \eta_1 - Q \sin \delta$   
 $x - \xi = f \quad y - \eta = g$

where  $\delta$  is the declination of the star and  $h = H - \lambda + t_s$ ,  $t_s$  being the sidereal equivalent of  $t$ .

If the time used is the true time of occultation the value of  $f^2 + g^2$  will be  $0.2725^2$  or  $0.07426$ . If  $f^2 + g^2$  exceeds or falls short of this constant the true time of occultation will be later or earlier than the assumed time if the phase concerned is a disappearance, the reverse being the case for a reappearance. The correction to the assumed time is

$$\pm \frac{30(f^2 + g^2 - k^2)}{kn \cos \psi} \text{ minutes}$$

where the upper and lower signs apply to immersion and emersion respectively, and where

$$a_0 = fQ + g\xi \sin \delta$$

$$kn \cos \psi = fx' + gy' - 0.2625 a_0$$

The coefficients  $a$  and  $b$  are given by

$$p = C^2 \rho \sin \phi' \sin h$$

$$q = C^2 \rho \sin \phi' \cos h$$

$$r = SC \rho \cos \phi' \cos \delta$$

$$b_0 = fp - gq \sin \delta - gr$$

$$J = \pm \frac{60^3 \sin \tau''}{kn \cos \psi}$$

$$a = Ja_0 \quad b = Jb_0$$

the upper and lower signs relating to immersion and emersion respectively, and  $S$  and  $C$  being tabulated in Table X.

The position angle  $P$ , measured from the north point of the Moon's disc in the direction N.E.S.W., is given by

$$\sin P = -\frac{f}{k} \quad \cos P = -\frac{g}{k} \quad \text{or} \quad \tan P = \frac{f}{g}$$

If the preliminary time is more than  $0^m.5$  in error the corrected time is used as the starting point of a fresh calculation. The reason for this is that the functions entering into the formulæ for  $a$ ,  $b$  and  $P$  are implicitly assumed to relate to the true times of immersion and emersion. The calculations are made to three significant figures and in practice all the quantities used are obtained from simple prepared tables, the multiplications being performed by means of Crelle's tables or a small calculating machine.

*Ephemeris for Physical Observations of the Sun* (Pages 564-567)

$P$  = position angle of the axis of rotation, measured eastward from the north point of the disc

$B_0$  = heliographic latitude of the centre of the disc

$L_0$  = heliographic longitude of the centre of the disc.

Heliographic longitudes are reckoned from the solar meridian that passed through the ascending node of the Sun's equator on the ecliptic on 1854 January 1, Greenwich mean noon\* (= J.D. 239 8220.0).

In the computation of the ephemeris the following elements by Carrington have been used:—

$I$  = inclination of the Sun's equator to the ecliptic =  $7^\circ 15'$

$\Omega$  = longitude of the ascending node of the Sun's equator on the ecliptic  
=  $73^\circ 40' + 50'' \cdot 25 (t - 1850)$

Sidereal period of rotation (mean solar days) =  $25^d \cdot 38$

It will be noticed that no allowance is made for the change in the plane of the ecliptic. The mean synodic rotation period is  $27^d \cdot 2753$ .

If  $\lambda$  is the longitude of the Sun

$$\tan x = -\tan \epsilon \cos(\text{Sun's apparent longitude})$$

$$\tan y = -\tan I \cos(\lambda - \Omega)$$

$$P = x + y$$

$$\sin B_0 = \sin I \sin(\lambda - \Omega)$$

$$\tan L = \cos I \tan(\lambda - \Omega)$$

$$L_0 = L \pm 180^\circ - \frac{360^\circ}{25 \cdot 38} \times \text{days elapsed since 1854 Jan. 1.0}$$

$x$ ,  $y$  and  $B_0$  being taken between the limits  $\pm \epsilon$ ,  $\pm I$  and  $\pm I$  respectively, and  $L$  in the same quadrant as  $\lambda - \Omega$ .

The equinox of  $\lambda$  is immaterial provided that  $\Omega$  is referred to the same equinox. It is therefore convenient to refer  $\lambda$  to the equinox of 1950.0, using the values on pages 38-45, and then  $\Omega$  becomes a constant. For working purposes the formulæ may be written

$$\tan x = -\tan \epsilon \cos(\text{Sun's apparent longitude})$$

$$\tan y = -0.12722 \cos(\lambda - 75^\circ \cdot 063)$$

$$P = x + y$$

$$\sin B_0 = 0.12620 \sin(\lambda - 75^\circ \cdot 063)$$

$$\tan L = 0.99200 \tan(\lambda - 75^\circ \cdot 063)$$

$$\text{or } \cot L = 1.00806 \cot(\lambda - 75^\circ \cdot 063)$$

$$L_0 = L + 112^\circ \cdot 766 + 14^\circ \cdot 18439 \text{ 716 } (243 \text{ 0000.5} - \text{J.D.})$$

The formula for  $\tan L$  or  $\cot L$  is used according as  $\tan(\lambda - 75^\circ \cdot 063)$  is numerically less than or greater than 1.

The value of  $L_0$  at any given G.M.T. may be found by subtracting from the tabulated value for 0<sup>h</sup> the amount given by the following table.

\* This is the definition of heliographic longitude that has always been used in the *Nautical Almanac*, although Carrington's zero meridian passed the ascending node twelve hours earlier than the above.

TABLE FOR INTERPOLATION OF  $L_0$

It is found convenient for certain classes of observation to number the synodic rotations in continuation of Carrington's (Greenwich Photo-Heliographic) series, of which No. 1 commenced on 1853 November 9. The rotations commencing in 1935 are

Rotation No.	Date of commencement	Rotation No.	Date of commencement
1088	Jan. 13.19	1095	July 23.04
1089	Feb. 9.53	1096	Aug. 19.27
1090	Mar. 8.86	1097	Sept. 15.52
1091	Apr. 5.16	1098	Oct. 12.80
1092	May 2.42	1099	Nov. 9.10
1093	May 29.64	1100	Dec. 6.41
1094	June 25.84	1101	Dec. 33.74

*Ephemeris for Physical Observations of the Moon (Pages 568-577)*

Selenographic longitudes are measured in the plane of the Moon's equator, the axis of reference being the radius of the Moon that passes through the mean centre of the visible disc. The axis therefore rotates with the Moon, and is not fixed in space. The positive direction of measurement is towards the west, i.e. towards *Mare Crisium*.

Selenographic latitudes are measured from the Moon's equator, positively towards the north, i.e. in the hemisphere containing *Mare Serenitatis*.

The *Earth's Selenographic Longitude and Latitude* are the selenographic co-ordinates of the centre of the disc as seen from the centre of the Earth. They are the sums of the optical and physical librations in longitude and latitude respectively.

The optical libration in longitude arises principally from the fact that, while the Moon's rotation on its axis is practically uniform, its angular velocity round the Earth is not uniform, since it moves in an elliptical orbit. The optical libration in latitude is due to the fact that the plane of the Moon's equator does not coincide with the plane of the orbit. At one time the northern pole of the Moon is presented to the Earth, while half a nodical month later the southern pole will be presented to approximately the same extent.

The *Physical Librations* arise because (i) the inclination of the Moon's equator to the Moon's orbit is not strictly constant (ii) the longitude of the ascending node of the Moon's equator on the ecliptic varies slightly on either side of the descending node of the Moon's orbit on the ecliptic and (iii) the rotation of the Moon on its axis is not absolutely uniform. These perturbations are due to the fact that the Moon's moments of inertia about three principal axes, two in the plane of the equator and the third coincident with the axis of rotation, are not the same.

When the libration in longitude, or the Earth's selenographic longitude, is positive the mean centre of the disc is displaced towards the east, thus exposing to view a region on the west limb. When the libration in latitude, or the Earth's selenographic latitude, is positive the mean centre of the disc is displaced towards the south, and a region on the north limb is exposed to view.

The *Sun's Selenographic Colongitude* is  $90^\circ$  (or  $450^\circ$ ) minus the Sun's selenographic longitude, and has, together with the *Sun's Selenographic Latitude*, been corrected for the effect of physical libration. It is numerically equal to the selenographic longitude of the morning terminator reckoned eastward from the mean centre of the disc. Hence its value is approximately  $270^\circ$ ,  $0^\circ$ ,  $90^\circ$  and  $180^\circ$  at New Moon, First Quarter, Full Moon and Last Quarter respectively. The longitude of the evening terminator differs by  $180^\circ$  from that of the morning terminator.

The *Position Angle of the Moon's Axis* is the angle that the lunar meridian through the centre of the visible disc makes with the declination circle through the same point. It has been corrected for the effect of physical libration.

The *Position Angle of the Terminator* is the position angle of the northern cusp, or the angle that the line joining the cusps makes with the declination circle through the centre of the Moon.

The *Fraction Illuminated* is equal to the fraction of the area of the Moon's disc illuminated, and also to the illuminated fraction of the diameter at right angles to the line of cusps.

The terminator is a semi-ellipse whose major axis is the line of cusps (i.e. the position angle of the major axis is the position angle of the terminator) and whose

semi-minor axis is equal to the semi-diameter multiplied by twice the difference between 0.50 and the fraction illuminated.

The formulæ used in computing the librations are given below. The value of  $I$  and the formulæ for physical libration are those given by Hayn in *Abhandlungen der Königlichen Sächsischen Gesellschaft der Wissenschaften*, 29 and 30 (1904 and 1907). The quantities  $i$ ,  $\Delta$ ,  $\Omega'$ ,  $\Gamma'$ ,  $\Omega$ ,  $\zeta$  and  $I$  have already been defined on page 787. In addition

$$\begin{aligned} g &= \text{Moon's mean anomaly} = \zeta - \Gamma' \\ g' &= \text{Sun's mean anomaly} \\ \lambda, \beta &= \text{longitude and latitude of the Moon} \\ \alpha, \delta &= \text{right ascension and declination of the Moon} \\ l', b' &= \text{optical librations in longitude and latitude} \\ l'', b'' &= \text{physical librations in longitude and latitude} \\ l = l' + l'' &= \text{Moon's libration in longitude} \\ &= \text{Earth's selenographic longitude} \\ b = b' + b'' &= \text{Moon's libration in latitude} \\ &= \text{Earth's selenographic latitude} \\ l_{\odot}, b_{\odot} &= \text{Sun's selenographic longitude and latitude} \\ C' &= \text{position angle of Moon's axis, without physical libration} \\ C'' &= \text{physical libration of the Moon's axis} \\ C = C' + C'' &= \text{position angle of the Moon's axis.} \end{aligned}$$

Then

$$\begin{aligned} \sin \mu &= \tan^2 \frac{1}{2} I \sin 2(\lambda - \Omega) \\ A &= \sin I \cos(\lambda - \Omega) \\ \tan B &= -\tan I \sin(\lambda - \Omega) \end{aligned}$$

$\mu$ ,  $A$  and  $B$  are tabulated on pages 568–569 with argument  $\lambda - \Omega$ .

$$\begin{aligned} l' &= \lambda + \mu + A b' - \zeta \\ b' &= B - \beta \\ \sin C' &= \sin i \cos(l' + \Delta + \zeta - \Omega) \sec \delta \\ &= -\sin i \cos(\alpha - \Omega') \sec b' \end{aligned}$$

If

$$\begin{aligned} M &= 0^{\circ}.040 \sin(\Gamma' - \Omega) - 0^{\circ}.003 \sin(\zeta - \Omega) \\ N &= 0^{\circ}.020 \cos(\Gamma' - \Omega) + 0^{\circ}.003 \cos(\zeta - \Omega) \end{aligned}$$

then

$$\begin{aligned} l'' &= 0^{\circ}.003 \sin g - 0^{\circ}.016 \sin g' - 0^{\circ}.005 \sin 2(\Gamma' - \Omega) + C' \sin b' \\ b'' &= M \cos l' + N \sin l' \\ C'' &= (M \sin l' - N \cos l') \sec b' \end{aligned}$$

The quantities  $\cos l'$  and  $\sec b'$  may be taken as 1, and the term  $C' \sin b'$  may be taken as  $0.018 C'' \times b'$  in degrees.

When the values of  $\lambda$ ,  $\beta$ ,  $\alpha$  and  $\delta$  used in the above formulæ represent the geocentric co-ordinates of the Moon the resulting values of  $l$ ,  $b$  and  $C$  will apply to the centre of the earth. To obtain the values applicable to an observer on the surface of the Earth the apparent co-ordinates of the Moon must be used. It will be found best to correct  $\alpha$  and  $\delta$  for parallax and then obtain the apparent longitude and latitude by conversion of the apparent right ascension and declination in the usual manner. The geocentric physical libration may be used unaltered.

The Sun's selenographic longitude and latitude are computed from similar formulæ in which the heliocentric co-ordinates of the Moon have been substituted for the geocentric co-ordinates.

If

 $\lambda_{\odot}$  = Sun's true longitude referred to true equinox

= mean longitude referred to equinox of 1935.0 + precession + nutation

 $R$  = radius vector of the Sun $\pi$  = Moon's equatorial horizontal parallax in minutes of arc $\lambda_{\text{M}}$  = Moon's heliocentric longitude $\beta_{\text{M}}$  = Moon's heliocentric latitude

then

$$\lambda_{\text{M}} = \lambda_{\odot} + 180^{\circ} + \frac{8.80 \times 57.296}{60 \pi R} \cos \beta \sin(\lambda_{\odot} - \lambda)$$

$$= \lambda_{\odot} + 180^{\circ} + F_0 F_1 \sin(\lambda_{\odot} - \lambda)$$

$$\beta_{\text{M}} = \frac{8.80 \beta}{60 \pi R} = F_0 \beta$$

 $\beta$        $F_1$ 

0.00

57.3

2.29

57.2

4.08

57.1

5.31

where  $F_0 = \frac{8.80}{60 \pi R}$  and can be tabulated in a double entrytable for every minute of  $\pi$  and every tenth day of the year.  
 $F_1 = 57.296 \cos \beta$  and is given in the accompanying critical table. $A$ ,  $B$  and  $\mu$  are found from the table on pages 568-569 with argument  $\lambda_{\text{M}} - \Omega$  and then

$$l'_{\odot} = \lambda_{\text{M}} + \mu + Ab'_{\odot} - \zeta$$

$$b'_{\odot} = B - \beta_{\text{M}}$$

$$l''_{\odot} = 0^{\circ}.003 \sin g - 0^{\circ}.016 \sin g' - 0^{\circ}.005 \sin 2(\Gamma' - \Omega) \\ + (M \sin l'_{\odot} - N \cos l'_{\odot}) \tan b'_{\odot}$$

$$b''_{\odot} = M \cos l'_{\odot} + N \sin l'_{\odot}$$

For the position angle  $T$  of the terminator and  $F$ , the fraction illuminated, two sets of formulæ are employed, as  $T$  cannot be checked near New Moon and Full Moon by the usual process of differencing.

$$\tan N = \frac{\tan \delta_{\odot}}{\cos(a_{\odot} - a)}$$

 $N$  being taken between the limits  $\pm 90^{\circ}$ .

$$\tan T = \cot(a_{\odot} - a) \sin(\delta - N) \sec N$$

 $T$  being taken between the limits  $\pm 90^{\circ}$ .

$$f = \cos(a_{\odot} - a) \cos \delta_{\odot} \cos(\delta - N) \sec N$$

$$F = \frac{1}{2}(1 - f)$$

The alternative formula for  $T$  is

$$\tan M = \frac{\tan b_{\odot}}{\sin(c_{\odot} + l)}$$

where  $c_{\odot}$  is the Sun's selenographic colongitude and  $M$  is taken between the limits  $\pm 90^{\circ}$ .

$$\tan(T - C) = \tan(c_{\odot} + l) \sin(M - b) \sec M$$

 $T - C$  being taken between the limits  $\pm 90^{\circ}$ .

$$T = C + (T - C)$$

Occasionally near New Moon or Full Moon this formula will yield the position angle of the southern cusp, i.e. an angle between  $90^\circ$  and  $270^\circ$ , in which case  $180^\circ$  must be added or subtracted.

It would be possible to compute  $f$  from

$$f = -\sin(c_0 + l) \cos b_0 \cos(M - b) \sec M$$

but in practice it is better to use

$$F = \text{haversine}(\lambda_0 - \lambda) = \text{haversine}(\lambda - \lambda_0)$$

which neglects the Moon's latitude, and is thus not strictly accurate, but serves as a check. The maximum error, at New or Full Moon, is 0.002, the value tending to be too small before First Quarter and too large after. It should be noted that the values published are geocentric, and may differ somewhat from those observed from the Earth's surface.

The Sun's altitude  $A$  at a point on the Moon in selenographic longitude  $\lambda_0$  and latitude  $\beta_0$  may be found from

$$\sin A = \sin b_0 \sin \beta_0 + \cos b_0 \cos \beta_0 \sin(c_0 + \lambda_0)$$

The position of the point may be defined by means of its direction cosines  $\xi, \eta, \zeta$ , the axis of  $\xi$  being that diameter of the Moon's equator which is  $90^\circ$  from the mean centre of the disc, and the positive direction being towards the west (i.e. as seen in the sky, not by an observer on the Moon), the axis of  $\eta$  being the Moon's polar axis, positive towards the north, and the axis of  $\zeta$  the diameter through the mean centre of the disc. Then

$$\sin A = \xi \cos c_0 \cos b_0 + \eta \sin b_0 + \zeta \sin c_0 \cos b_0$$

Neither formula is convenient when the Sun's altitude is very great, for an angle near  $90^\circ$  cannot easily be determined accurately from its sine. However, when the Sun is high it is not necessary to compute its altitude with great accuracy, as the shadows are then inconspicuous.

An ephemeris of the crater Mösting A is given each year in the *Berliner Jahrbuch*.

#### *Illuminated Discs of Mercury and Venus* (Pages 578–579)

The notation is explained on pages 578–579.  $\theta$  is the position angle of the arc of the great circle from the planet to the Sun increased by  $90^\circ$ . If on the disc of the planet an arrow be drawn towards position angle  $\theta$ , the illuminated portion of the disc will be on the right of the arrow. When  $\theta$  is less than  $180^\circ$  the north limb of the planet is full; when greater the south limb. When  $\theta$  is between  $90^\circ$  and  $270^\circ$  limb II, i.e. the following or east limb, is full. The position angle of the direction of greatest defect of illumination is  $\theta + 90^\circ$ .

The terminator is a semi-ellipse whose major axis is a diameter of the planet in position angle  $\theta$  and whose semi-minor axis is of length S.D.  $\times$  (twice the difference between  $k$  and 0.500) in position angle  $\theta - 90^\circ$  when  $k$  is less than 0.5, and  $\theta + 90^\circ$  when  $k$  is greater than 0.5.

When  $i$  is greater than  $90^\circ$ ,  $k$  is less than 0.5, i.e. the planet is horned, and the correction of an observation of the cusp for defective illumination in declination is S.D.  $\times (1 \pm \cos \theta)$ , the sign being so taken as to make the quantity within the bracket less than unity.

When  $i$  is less than  $90^\circ$ ,  $k$  is greater than 0.5, i.e. the planet is gibbous. If angles  $\phi$  and  $\psi$  (in the first quadrant) are found from

$$\sin \phi = \sin i \cos \theta$$

$$\sin \psi = \sin i \sin \theta$$

the correction for defective illumination in right ascension is

Sidereal time of S.D. passing meridian  $\times (1 - \cos \phi)$

and that in declination is S.D.  $\times (1 - \cos \psi)$ . When the corrections are very small they are sensibly equal to

Sidereal time of S.D. passing meridian  $\times \frac{1}{2} \sin^2 i \cos^2 \theta$

and S.D.  $\times \frac{1}{2} \sin^2 i \sin^2 \theta$

Using  $\alpha$  and  $\delta$  for the co-ordinates of the planet:—

$$\sin D \sin \theta = \cos \delta \sin \delta_0 - \sin \delta \cos \delta_0 \cos(\alpha - \alpha_0)$$

$$\sin D \cos \theta = \cos \delta_0 \sin(\alpha - \alpha_0)$$

in which  $\sin D$  is always positive, as  $D$  is the elongation of the planet from the Sun, and is less than  $90^\circ$ .

$$\sin i = \frac{R \sin D}{r} = \frac{R \cos \delta_0 \sin(\alpha - \alpha_0) \sec \theta}{r}$$

$R$  and  $r$  being the radii vectores of the Earth and planet respectively.

If  $i$  is near  $90^\circ$  it is not easily determined from its sine. In that case

$$\sin S = \frac{\Delta \sin D}{r} = \frac{\Delta \cos \delta_0 \sin(\alpha - \alpha_0) \sec \theta}{r}$$

$\Delta$  being the distance of the planet from the Earth and  $S$  being in the first quadrant in all cases where it is necessary to use it. Then

$$i = 180^\circ - D - S$$

$$h = \frac{1}{2}(1 + \cos i) = 1 - \text{haversine } i$$

The *Brilliancy of the Disc* is really the brightness as compared with that of a fictitious planet of semi-diameter  $r''$ , situated at unit distance from the Sun and at the same distance from the Earth as the planet, and supposed to be fully illuminated and to have the same albedo as the planet. Hence

$$L = \frac{s^2 h}{r^2}$$

where  $s$  = semi-diameter. With the adopted values  $3''.34$  and  $8''.41$  of the semi-diameters at unit distance

$$L = \frac{11.16 h}{r^2 \Delta^2} \quad \text{for Mercury}$$

$$= \frac{70.73 h}{r^2 \Delta^2} \quad \text{for Venus.}$$

The *Stellar Magnitudes* are computed from Müller's formulæ:—

$$\text{For Mercury} \quad +1.16 + 5 \log r\Delta + 0.02838 (i - 50^\circ) + 0.00010 23 (i - 50^\circ)^2$$

$$\text{For Venus} \quad -4.00 + 5 \log r\Delta + 0.01322 i + 0.00000 04247 i^2$$

where  $i$  is measured in degrees.

*Ephemeris for Physical Observations of Mars* (Pages 580–585)

The *Light-Time* is the time taken by light to travel from the planet to the Earth, the time required to travel unit distance being taken as 498<sup>s</sup>.58.

The *Stellar Magnitude* is based on Müller's formula

$$-1.30 + 5 \log r\Delta + 0.01486 i$$

where  $i$  is measured in degrees.

- $P$  = position angle of the axis of rotation, measured eastward from the north point of the disc
- $A_{\odot}$ ,  $A_0$  = areocentric right ascension of the Earth and Sun respectively, measured in the plane of the planet's equator from its vernal equinox
- $D_{\odot}$ ,  $D_0$  = areocentric declinations of the Earth and Sun respectively, referred to the planet's equator
- $\odot_s$  = areocentric longitude of the Sun, measured in the plane of the planet's orbit from its vernal equinox
- $k$  = ratio of the area of the illuminated portion of the apparent disc to the area of the entire apparent disc regarded as circular
- $i$  = angle between the Sun and Earth as seen from Mars
- $q$  = angular value of the greatest defect of illumination as seen from the Earth
- $Q$  = position angle of the point of greatest defect of illumination, measured from the north point of the disc. The position angle of the line of cusps is  $Q \pm 90^\circ$ .

The *Diameter* is based on a diameter at unit distance of  $9''.36$ .

The column *Central Meridian* gives the longitude of the meridian that passes through the centre of the disc, measured from the adopted zero meridian. No correction is made for phase.

The column *G.M.T. of Transit of Zero Meridian* gives the G.M.T. of every transit of the zero meridian across the actual centre of the disc.

All the above quantities have been corrected for aberration, so that in using them they should be interpolated to the actual time of observation.

The assumed position of the north pole of Mars at the beginning of year  $t$  is

$$\begin{aligned}\alpha_0 &= 21^h 10^m 00^s + 1^s.565 (t - 1905.0) \\ \delta_0 &= 54^\circ 30' 00'' + 12''.60 (t - 1905.0)\end{aligned}$$

as given by Lowell and Crommelin (*M.N.R.A.S.*, 66, 56). The zero meridian may be defined by adopting as the longitude of the central meridian on 1897 May 15.0 G.M.T. the value  $52^\circ.01$ , as given by Marth (*M.N.R.A.S.*, 56, 403). However, on account of changed values for the position of the axis of Mars, the ephemeris is actually calculated on the assumption that the longitude of the central meridian on 1909 January 15.0 was  $344^\circ.41$ , as given in the *Nautical Almanac*, and based on the present value of the position of the axis. The daily motion in longitude of the zero meridian is taken as  $350^\circ.89202$ , which corresponds to a period of rotation of  $24^h 37^m 22^s.654$ . The daily motion and period of rotation are regarded as being relative to the planet's true equinox; in other words the period is the Martian sidereal day, and differs slightly from the true period of axial rotation on account of a slight precession of the Martian equinoxes.

The formulæ on which the ephemeris is based are given below. In addition to the quantities already defined

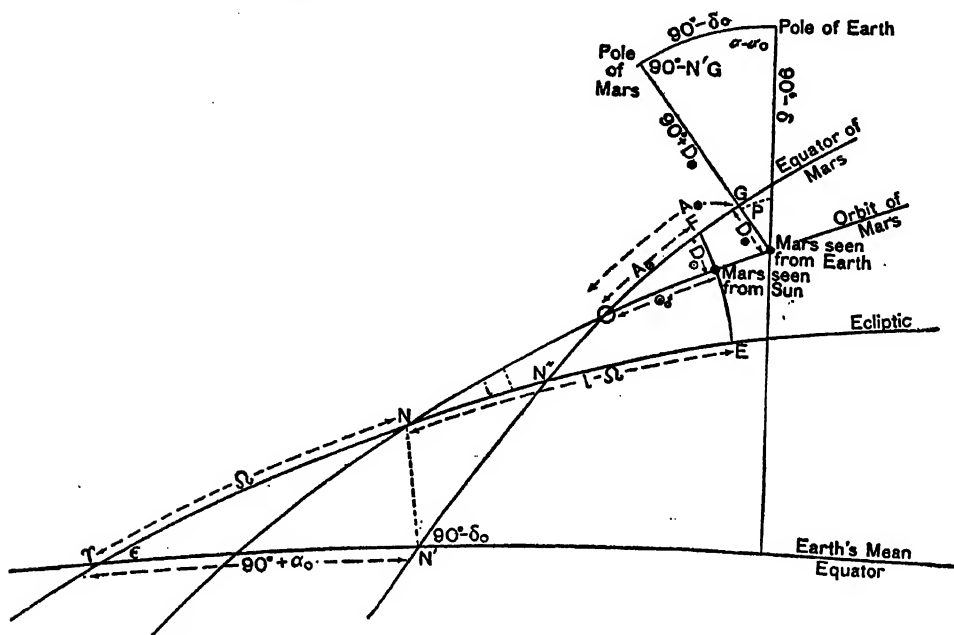

- $\alpha$ ,  $\delta$ ,  $\Delta$  = geocentric equatorial co-ordinates of Mars
- $l$ ,  $b$ ,  $r$  = heliocentric ecliptic co-ordinates of Mars
- $\Omega$ ,  $i$  = node and inclination to the ecliptic of the orbit of Mars
- $\epsilon$  = mean obliquity.

In the diagram, which shows the projections on the celestial sphere of the four planes involved, O is the ascending node of the equator of Mars on the orbit of Mars,

## EXPLANATION, 1935

i.e. the planet's autumnal equinox. The geocentric or heliocentric longitude of Mars measured in the plane of its equator from this autumnal equinox will be the same as the areocentric right ascension of the Earth or Sun respectively, measured in the same plane from the vernal equinox. The geocentric or heliocentric declinations of Mars measured from the plane of the planet's equator will be the same numerically as the areocentric declinations of the Earth and Sun respectively, but will be reversed in sign.

The ascending node of the equator of Mars on the Earth's mean equator will be in R.A.  $90^\circ + \alpha_0$ , and the inclination of the two equators will be  $90^\circ - \delta_0$ .

The adopted values of  $\Omega$  and  $i$  are taken from Newcomb's orbit of Mars, with Ross's corrections

$$\begin{aligned}\Omega &= 48^\circ 47' 11''.19 + 2775''.57 T - 0''.005 T^2 - 0''.0192 T^3 \\ i &= 1^\circ 51' 01''.20 - 2''.430 T + 0''.0454 T^2\end{aligned}$$

where  $T$  is measured in Julian centuries from 1900 January 0.0 G.M.T. = J.D. 241 5020.0.

It is necessary to know three quantities that change slowly—the arcs  $NO$  and  $N'O$  and the angle  $NON'$ . In the triangle  $N\gamma N'$ ,  $\gamma N = \Omega$ ,  $N\gamma N' = \epsilon$  and  $\gamma N' = 90^\circ + \alpha_0$ , all of which are known, so that the triangle can be completely solved. Then

$$ONN' = 180^\circ - \gamma NN' + i \quad NN'O = 90^\circ - NN'\gamma + \delta_0$$

and  $NN'$  is now known, so that the three quantities may be found.

It has been assumed that the Earth's mean equator has been used, whereas actually the point  $N'$  should be the intersection of the Earth's true equator and the equator of Mars. The only quantity affected by nutation is  $N'O$ , which is equal to  $N'N'' + N''O$ , the part  $N''O$  not being affected. Differentiating the triangle  $N''\gamma N'$

$$\Delta N'N'' = \cos(90^\circ + \alpha_0) \sin \epsilon \sec \delta_0 \Delta \psi + \sin(90^\circ + \alpha_0) \sec \delta_0 \Delta \epsilon$$

where

$\Delta\psi$  = nutation in longitude

$\Delta\epsilon$  = nutation in obliquity =  $-B$

The effect of nutation on  $N'N''$  may amount to  $\pm 0^\circ.004$ , and the annual change of this effect cannot exceed  $0^\circ.001$ . If we put

$$X = 90^\circ - N'O$$

then, if  $\Delta\psi$  and  $B$  are in seconds of arc,

$$X = 90^\circ - N'O \text{ for mean equator} - 0^\circ.00013 \Delta\psi + 0^\circ.00036 B$$

and may be tabulated for the beginning of each year.

In the triangle formed by Mars and the poles of the Earth and Mars, the sides and angles will be as shown on the diagram. Now

$$\begin{aligned} A_\oplus + 180^\circ &= N'G - N'O + 180^\circ \\ &= 180^\circ - (90^\circ - N'G) + (90^\circ - N'O) \\ &= R + X \end{aligned}$$

where  $R = 180^\circ - (90^\circ - N'G)$ . To solve the triangle

$$\begin{aligned} \cos D_\oplus \sin R &= \cos \delta \sin(\alpha - \alpha_0) \\ \cos D_\oplus \cos R &= -\sin \delta \cos \delta_0 + \cos \delta \sin \delta_0 \cos(\alpha - \alpha_0) \\ \sin D_\oplus &= -\sin \delta \sin \delta_0 - \cos \delta \cos \delta_0 \cos(\alpha - \alpha_0) \\ \cos D_\oplus \sin P &= -\cos \delta_0 \sin(\alpha - \alpha_0) \\ \cos D_\oplus \cos P &= \cos \delta \sin \delta_0 - \sin \delta \cos \delta_0 \cos(\alpha - \alpha_0) \end{aligned}$$

In these equations  $\alpha$  and  $\delta$  are the apparent right ascension and declination of the planet, so that no further correction for aberration is necessary. But  $\alpha_0$  and  $\delta_0$  also should strictly be referred to the true equator and equinox. They may first be reduced to the equinox of the beginning of the year by applying the precessions given, which include the effect of a small precession of the Martian vernal equinox. The further reductions to the equinox of date would then be

$$\begin{aligned} \Delta\alpha_0 &= Aa + Bb + (15.565 - a)\tau \\ \Delta\delta_0 &= Aa' + Bb' + (12.60 - a')\tau \end{aligned}$$

These amount to

$$\begin{aligned} \Delta\alpha_0 &= 1.81 A + 0.070 B - 0.24 \tau && \text{in seconds of time} \\ \Delta\delta_0 &= 0.0041 A + 0.0002 B - 0.0006 \tau && \text{in degrees.} \end{aligned}$$

Denoting by  $M'$  the position of Mars as seen from the Sun, and by  $M'E$  the perpendicular from Mars to the ecliptic,

$$\begin{aligned} \odot_s &= OM' = NM' - NO \\ NE &= rE - rN = l - \Omega \\ \tan NM' &= \tan(l - \Omega) \sec i \end{aligned}$$

or, since  $i$  is very small,

$$NM' = l - \Omega + 0^\circ.015 \sin 2(l - \Omega)$$

A correction for aberration must be applied to  $NM'$ . This will be strictly equal to the daily motion of Mars in heliocentric longitude multiplied by the time in days taken by light to travel from the Sun to Mars, and then back to the Earth. Since the eccentricity  $e$  is small, being only 0.093,

$$dv = dM (1 + 2e \cos M) \quad r = a(1 - e \cos M)$$

so that

$$r dv = a dM (1 + e \cos M)$$

Hence the portion of the aberration relating to the distance from Mars to the Sun fluctuates only 9 per cent on either side of its mean, which is  $0^\circ.005$ . The

## EXPLANATION, 1935

average distance of Mars from the Earth during the period covered by the physical ephemeris may be taken as 0.7 units, giving a further correction of 0°.002. If we put

$$Y = NO + 0°.007$$

then

$$\odot_s = l - \Omega + 0°.015 \sin 2(l - \Omega) - Y$$

If M'F is the perpendicular to the equator of Mars

$$OF = A_\odot$$

$$M'F = D_\odot$$

so that

$$\tan A_\odot = \tan \odot_s \cos Z$$

$$\sin D_\odot = \sin \odot_s \sin Z$$

where  $Z$  is the angle  $NON' = FOM'$  = the obliquity of the Martian ecliptic.

The values of the slowly changing quantities for the years 1930 to 1950 are shown in the table below;  $i$  is 1°.850 during this period.

Year	$\alpha_0$	$\delta_0$	$\Omega$	$X$	$Y$	$\sin Z$	$\cos Z$
1930.0	21 10 39.1	54.588	49.018	44.085	38.951	0.40640	0.91370
1931.0	40.7	.591	.025	.079	.955	.40640	.91369
1932.0	42.3	.594	.033	.073	.958	.40641	.91369
1933.0	43.8	.598	.041	.067	.962	.40641	.91369
1934.0	45.4	.602	.049	.062	.966	.40642	.91369
1935.0	21 10 47.0	54.605	49.056	44.057	38.970	0.40642	0.91369
1936.0	48.5	.608	.064	.052	.974	.40643	.91368
1937.0	50.1	.612	.072	.048	.978	.40643	.91368
1938.0	51.6	.616	.079	.044	.982	.40644	.91368
1939.0	53.2	.619	.087	.040	.986	.40644	.91368
1940.0	21 10 54.8	54.622	49.095	44.036	38.990	0.40645	0.91368
1941.0	56.3	.626	.103	.032	.994	.40645	.91367
1942.0	57.9	.629	.110	.027	38.998	.40646	.91367
1943.0	10 59.5	.633	.118	.022	39.002	.40646	.91367
1944.0	11 01.0	.636	.126	.017	.006	.40646	.91367
1945.0	21 11 02.6	54.640	49.133	44.011	39.010	0.40647	0.91366
1946.0	04.2	.643	.141	44.005	.015	.40647	.91366
1947.0	05.7	.647	.149	43.998	.019	.40648	.91366
1948.0	07.3	.650	.157	.991	.023	.40648	.91366
1949.0	08.9	.654	.164	.985	.027	.40649	.91366
1950.0	21 11 10.4	54.657	49.172	43.978	39.031	0.40649	0.91365

For the quantities on the right-hand pages

$$\sin D \sin Q = \cos \delta_0 \sin(\alpha - \alpha_0)$$

$$\sin D \cos Q = -\cos \delta \sin \delta_0 + \sin \delta \cos \delta_0 \cos(\alpha - \alpha_0)$$

in which  $\sin D$  is always positive, as  $D$  is the elongation of the planet from the Sun.

$$\sin i = \frac{R \sin D}{r} = \frac{R \cos \delta_0 \sin(\alpha - \alpha_0) \operatorname{cosec} Q}{r}$$

$$h = \frac{1}{2}(1 + \cos i) = 1 - \text{haversine } i$$

$$\text{Diameter} = \frac{9''.36}{\Delta}$$

$$q = \text{diameter} \times (1 - h)$$

If

$V$  = Martian hour angle of the vernal equinox for a point on the zero meridian  
= sidereal time for the "Greenwich" of Mars

then

$V - A_{\oplus}$  = Martian hour angle of the Earth for a point on the zero meridian  
= longitude of the central meridian as seen from the Earth.

To allow for aberration  $V$  must be diminished by the amount of the angular rotation in the planet's light-time, i.e. by  $2^{\circ} \cdot 025 \Delta$ , so that

Longitude of C.M. =  $V + 180^{\circ} - (A_{\oplus} + 180^{\circ})$  - angular rotation in light-time.

To obtain the value of  $V + 180^{\circ}$

Longitude of C.M. 1909 January 15.0	344.41 <sup>o</sup>
$A_{\oplus} + 180^{\circ}$ (from N.A. for 1909)	337.38
Rotation in light-time	4.055
Sum = $V + 180^{\circ}$ on 1909 January 15.0	325.845

Hence

$$V + 180^{\circ} = 325^{\circ} \cdot 845 + 350^{\circ} \cdot 89202 (\text{J.D.} - 241\ 8322 \cdot 0)$$

The G.M.T. of transit of the zero meridian is found by determining from the longitudes of the central meridian at 0<sup>h</sup> the time at which the longitude of the central meridian is 0<sup>o</sup>.

#### *Satellites of Mars (Pages 586-589)*

The data given are derived from the elements given by H. Struve in *Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften*, 1911, page 1073.

The elements are defined as follows:—

$N$  = ascending node on the Earth's mean equator

$J$  = inclination to the Earth's mean equator

$n$  = tropical mean daily motion

$t_e$  = number of days elapsed since the epoch

$\tau$  = time expressed in Besselian years

$l$  = mean longitude, measured in the Earth's mean equator from the equinox to the ascending node of the orbit, and then in the orbit itself

$\Pi$  = longitude of pericentre, measured in the same way as  $l$

$e$  = eccentricity

$a(\Delta)$  = semi-major axis of orbit at unit distance.

The symbols  $N$  and  $J$  are used without suffix for the satellite and with suffix  $\tau$  to define an auxiliary fixed plane, used for defining the plane of the orbit.

*Elements of Phobos.*

$$\left. \begin{aligned} N_1 &= 47^\circ 03'.7 \\ J_1 &= 37^\circ 24'.0 \end{aligned} \right\} \text{Equator and equinox of 1880.0}$$

$$\left. \begin{aligned} (N - N_1) \sin J_1 &= 57'.5 \sin \{359^\circ.2 - 158^\circ.0(\tau - 1894.80)\} \\ J - J_1 &= 57'.5 \cos \{359^\circ.2 - 158^\circ.0(\tau - 1894.80)\} \end{aligned} \right\} \text{Equator and equinox of 1880.0; epoch } \tau$$

$$l_0 = 296^\circ.40 \quad \text{Epoch 1894 October 0.0 G.M.T. = J.D. 241 3102.0}$$

$$n = 1128^\circ.84406$$

$$l = l_0 + nt + 0^\circ.32 \sin \{359^\circ.2 - 158^\circ.0(\tau - 1894.80)\}$$

$$\Pi = 279^\circ.1 + 158^\circ.0(\tau - 1894.80)$$

$$e = 0.0170$$

$$a(\Delta) = 12''.938$$

*Elements of Deimos.*

$$\left. \begin{aligned} N_1 &= 46^\circ 01'.2 \\ J_1 &= 36^\circ 44'.0 \end{aligned} \right\} \text{Equator and equinox of 1880.0}$$

$$\left. \begin{aligned} (N - N_1) \sin J_1 &= 1^\circ 44'.0 \sin \{27^\circ.3 - 6^\circ.374(\tau - 1894.80)\} \\ J - J_1 &= 1^\circ 44'.0 \cos \{27^\circ.3 - 6^\circ.374(\tau - 1894.80)\} \end{aligned} \right\} \text{Equator and equinox of 1880.0; epoch } \tau$$

$$l_0 = 186^\circ.17 \quad \text{Epoch 1894 October 0.0 G.M.T. = J.D. 241 3102.0}$$

$$n = 285^\circ.16196$$

$$l = l_0 + nt + 0^\circ.58 \sin \{27^\circ.3 - 6^\circ.374(\tau - 1894.80)\}$$

$$\Pi = 231^\circ + 6^\circ.374(\tau - 1894.80)$$

$$e = 0.0031$$

$$a(\Delta) = 32''.373$$

The elements of the equator of Mars, as given by Struve, are

$$N_0 = 47^\circ 04'.4 + 0'.463(\tau - 1880.0) \quad \text{Mean equator and}$$

$$J_0 = 37^\circ 24'.4 - 0'.239(\tau - 1880.0) \quad \text{equinox of } \tau$$

The node  $N'_0$  and the inclination  $J'_0$  referred to the orbit of Mars at the epoch 1880.0 are

$$N'_0 = 81^\circ 00'.3$$

$$J'_0 = 25^\circ 10'.2$$

where  $N'_0$  is measured from the ascending node of the orbit of Mars on the Earth's mean equator. The quantity  $J'_0$  is the obliquity of the Martian equator. The annual precession of the Martian equinoxes is  $-7''.07$ .

The quantities on pages 587 and 589, in conjunction with the times of greatest eastern elongation on pages 586 and 588, enable an approximate position angle  $p$  and distance  $s$  of the satellite from the centre of the primary to be determined. The apparent orbit of the satellite is an ellipse whose semi-major axis is of length  $\frac{a(\Delta)}{\Delta}$

and in position angle  $P$ .  $P_0$  is the value of  $P$  at some arbitrary date near opposition, and is the quantity appearing in the column  $p^1$  for the time 0<sup>h</sup> 00<sup>m</sup> from eastern elongation. The angle through which the satellite has moved since eastern elongation, increased by  $P_0$ , is the quantity  $p^1$ .  $F$  is the ratio of the actual distance of the satellite from the primary to the distance at elongation.  $a$  is the semi-major axis in seconds of arc at the mean distance ( $\Delta$ ) of Mars, so that  $a(\Delta)$  is the semi-major axis at unit distance.  $\Delta$  is the distance of Mars from the Earth.

As the eccentricity of the apparent orbit of the satellite is continually varying it is evident that the quantities  $p^1$  and  $F$  are also changing. The values given are

accurate in the neighbourhood of opposition. The positions of the satellites deduced from the data given are intended to serve for identification purposes only, and not for the comparison of observations with theory.

## *Ephemeris for Physical Observations of Jupiter* (Pages 590-595)

The definitions of the quantities tabulated are similar to those already given for Mars. The zenocentric longitude of the Sun is not tabulated. It may be noted that  $Q$  is also the position angle of the shadows of the satellites measured from the satellites themselves.

The assumed position of the north pole of Jupiter at the beginning of year  $t$  is

$$\begin{aligned} \alpha_0 &= 17^{\text{h}} 52^{\text{m}} 00^{\text{s}}.84 + 0^{\text{s}}.247(t - 1910.0) \\ \delta_0 &= 64^{\circ} 33' 34''.6 - 0''.60(t - 1910.0) \end{aligned}$$

which has been deduced from the position given by Damoiseau for 1750 in *Tables Écliptiques des Satellites de Jupiter*.

The position of the zero meridian is defined by the following adopted values of the longitude of the central meridian on 1897 July 14.0 G.M.T.

System I	47°·31	System II	96°·58
----------	--------	-----------	--------

these being the last values published by Marth (*M.N.R.A.S.*, 56, 523) before his death. The adopted daily motions of the zero meridians (relative to the vernal equinox of Jupiter) and the resulting periods are

System I	877°·90	9 <sup>h</sup> 50 <sup>m</sup> 30 <sup>s</sup> ·003
System II	870°·27	9 <sup>h</sup> 55 <sup>m</sup> 40 <sup>s</sup> ·632

The tables of the *Movement of the Central Meridian* are based on the mean daily synodic rotation during the period when the planet is observable, namely 877°·95 for System I and 870°·30 for System II.

The equatorial diameter at unit distance is taken as 196"·94, and the polar diameter as  $\frac{1}{4}$  of this, or 183"·81. The excess of the equatorial diameter over the polar is calculated as follows:—

$D_{\odot}$	$F$	$\cos \epsilon_0 = \frac{1}{4}$
0·00	0·0667	$\sin \epsilon = \sin \epsilon_0 \cos D_{\odot}$
0·89	0·0666	Excess = diameter $\times (1 - \cos \epsilon)$
2·35	0·0665	= diameter $\times F$
3·21	0·0664	
3·40		

where  $F$  is tabulated in the accompanying critical table with argument  $D_{\odot}$ .

The magnitude is computed from Müller's formula

$$-8.93 + 5 \log r\Delta$$

The *Correction for Phase*, which is numerically equal to  $57^{\circ} \cdot 3 (1 - k)$  or  $57^{\circ} \cdot 3 \sin^2 \frac{1}{2} i$ , is the correction that must be applied to the longitude of the central meridian to give the longitude of the meridian that bisects the apparent or illuminated disc. In the columns on page 591 this correction has not been applied, but on pages 592 and 594 it has already been applied.

The zenographical latitude  $D'_\oplus$  of the apparent centre of the disc is given by

$$\tan D'_\oplus = \sec^2 \epsilon_0 \tan D_\oplus = 1.148 \tan D_\oplus$$

or, since  $D_\oplus$  cannot exceed  $\pm 3^\circ.4$

$$D'_\oplus = 1.148 D_\oplus$$

Similarly the eccentric angle  $D'_\oplus$  at the centre of Jupiter of the apparent centre of the disc is given by

$$D'_\oplus = \sec \epsilon_0 D_\oplus = 1.071 D_\oplus$$

If the angular distance from the centre of the disc of a spot on the central meridian be denoted by  $d$  (positive to the north) and the polar semi-diameter by  $b$ , the zenocentric latitude  $\beta$  or the zenographical latitude  $\beta'$  of the spot may be determined from

$$\sin \theta = \frac{d}{b}$$

$$\beta' = \theta + D'_\oplus$$

$$\tan \beta = \cos \epsilon_0 \tan \beta' = 0.9333 \tan \beta'$$

$$\tan \beta'' = \sec \epsilon_0 \tan \beta' = 1.0714 \tan \beta'$$

#### *Satellites of Jupiter* (Pages 596-621)

The data concerning the four brighter satellites are derived from Sampson's *Tables of the Four Great Satellites of Jupiter* (London, 1910). Certain simplifications of the tables, as described by H. Andoyer in *Bulletin Astronomique*, 32, 177 (1915) have been adopted for ephemeris purposes, so that the data given are not intended for the rigorous comparison of observation with theory.

The elongations of satellite V are derived from elements deduced by J. Robertson in 1895, and published in the *Connaissance des Temps* each year. The differential co-ordinates of satellites VI and VII are derived from elements and tables given by F. E. Ross in *Lick Observatory Bulletin*, Vol. IV, No. 112 (1906) and in *Astronomische Nachrichten* 4175 (1907).

Extensive tables to facilitate the computation of accurate positions relative to Jupiter of the four brighter satellites are given each year in the *Connaissance des Temps*.

All the times given have been corrected for light-time, and, where necessary, for the phase of the planet. In the diagram on page 596 the central ellipse represents the disc of Jupiter, and the inner orbit is that of satellite V.

Before opposition eclipses may be observed on the west side of Jupiter, after opposition on the east. Before opposition the immersions of satellite I in the shadow may be observed, while after that date the emersions only are visible. The same is true in general of satellite II, although occasionally both phenomena may be seen. In the case of satellites III and IV both phases are usually visible, except near opposition. The points of immersion into and emersion from the shadow are shown pictorially at the foot of the right-hand page for each month, while at the foot of the left-hand page the rectangular co-ordinates are given, in units of the equatorial radius of Jupiter, the axis of  $x$  being parallel to the equator of Jupiter and directed positively to the east, while the axis of  $y$  is directed positively to the north pole of Jupiter. The suffix 1 refers to an immersion or beginning of the eclipse, and the suffix 2 to an emersion or end of the eclipse.

In the diagrams of the configurations of the four brighter satellites Jupiter is represented by a light disc in the centre of the page, and the relative positions of the satellites at the times stated above the diagrams are indicated by dots. The designation of each satellite is shown by a numeral placed to the right or left of the dot, the motion of the satellite at the instant in question being always towards the numeral. In constructing the diagrams the latitudes of the satellites are considered to be zero, except when two or more of them happen to be at nearly the same distance from the planet, in which case they are placed one above the other, as they would appear in the sky, although no attempt has been made to represent the distance between them to scale. A light disc, accompanied by a numeral, placed at the side of the diagram indicates that the satellite is projected on to the disc of Jupiter; in other words a transit is in progress. A dark disc indicates that the satellite is invisible, either because it is occulted by Jupiter, or because it is immersed in the shadow. The disc is placed on the right or left according as the satellite is on the right or left of the centre of Jupiter at the moment for which the configuration is given.

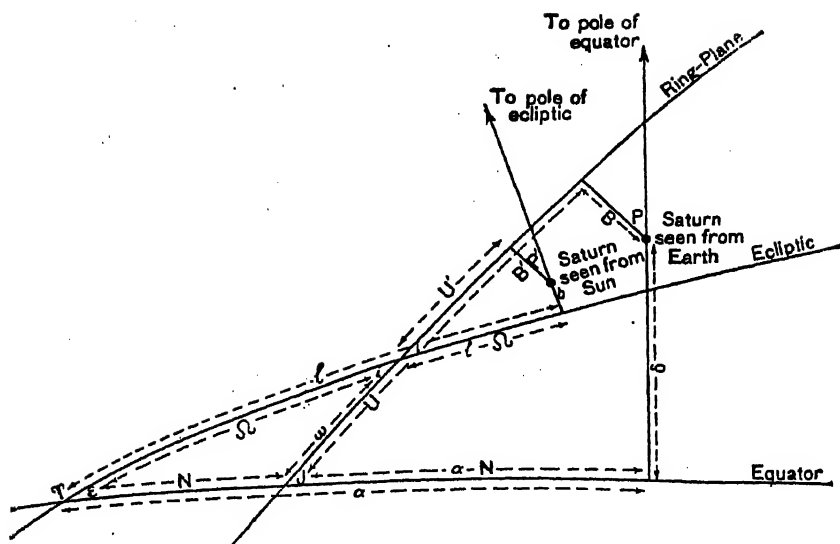

*Rings of Saturn* (Pages 622-624)

The elements tabulated are defined as follows:—

- $a, b$  = axes of the outer ellipse of the outer ring
- $P$  = position angle of the northern semi-minor axis of the rings, measured from the north and positive towards the east
- $B$  = saturnicentric latitude of the Earth referred to the ring-plane and positive towards the north
- $U$  = geocentric longitude of Saturn, measured in the ring-plane from its ascending node on the Earth's mean equator.  $U + 180^\circ$  is the saturnicentric longitude of the Earth measured in the ring-plane from its ascending node on the Earth's mean equator.
- $P'$  = the angle that the northern semi-minor axis of the rings makes with the latitude circle through the centre of Saturn, as seen from the Sun and positive towards the east
- $B'$  = saturnicentric latitude of the Sun referred to the ring-plane and positive towards the north
- $U'$  = heliocentric longitude of Saturn, measured in the ring-plane from its ascending node on the ecliptic
- $\Omega$  = ascending node of the ring-plane on the ecliptic, measured from the mean equinox
- $i$  = inclination of the ring-plane to the ecliptic
- $N$  = ascending node of the ring-plane on the Earth's mean equator, measured from the mean equinox
- $J$  = inclination of the ring-plane to the Earth's mean equator
- $\omega$  = the angular distance in the ring-plane from its ascending node on the Earth's mean equator to its ascending node on the ecliptic.

The geometrical significance of the above quantities may be studied in the accompanying diagram. They are all tabulated for the moment when light left Saturn; to compare observed quantities with those tabulated the light time should be subtracted from the time of observation.

The outer diameter of the rings at distance 9.53887 units is, according to H. Struve (*Beobachtungen der Saturnstrabanten*, *Publications de l'Observatoire Central Nicolas*, vol. xi, page 226),  $39''.35$ , corresponding to a diameter of  $375''.35$  at unit distance. The minor axis  $b$  of the rings is  $a \sin B$ . The factors by which  $a$  and  $b$  must be multiplied to give the other dimensions of the rings are given below. The factor for the dusky ring is based on the observations of various astronomers, and the remainder on Bessel's data.

The inner ellipse of the outer ring	0.8801
The outer ellipse of the inner ring	0.8599
The inner ellipse of the inner ring	0.6650
The inner ellipse of the dusky ring	0.5486

The adopted position of the ring-plane, referred to the mean ecliptic and equinox of 1889.25, is, according to H. Struve (*loc. cit.*, page 166),

$$\Omega = 167^\circ 57'.0 \quad i = 28^\circ 05'.6$$

To compute  $N$ ,  $J$  and  $\omega$

$$\begin{aligned} \sin J \sin N &= \sin i \sin \Omega \\ \sin J \cos N &= \cos i \sin \epsilon + \sin i \cos \epsilon \cos \Omega \\ \cos J &= \cos i \cos \epsilon - \sin i \sin \epsilon \cos \Omega \\ \sin J \sin \omega &= \sin \epsilon \sin \Omega \\ \sin J \cos \omega &= \sin i \cos \epsilon + \cos i \sin \epsilon \cos \Omega \end{aligned}$$

The quantities  $\Omega$  and  $i$  must be corrected for precession and shift of the ecliptic. They vary slowly, as do  $N$ ,  $J$  and  $\omega$ , so may be expressed by a time power series, in which  $T$  is reckoned in tropical centuries from 1900.0.

$$\Omega = 168.09980 + 1.39351 T + 0.00041 T^2$$

$$i = 28.09193 - 0.01302 T$$

$$N = 126.40593 + 3.99960 T + 0.21732 T^2 + 0.01011 T^3 + 0.00015 T^4$$

$$J = 6.92944 - 0.44818 T + 0.01163 T^2 + 0.00078 T^3 + 0.00004 T^4$$

$$\omega = 42.86155 - 2.74230 T - 0.21709 T^2 - 0.01010 T^3 - 0.00015 T^4$$

The values for the years 1920-1950 are given in the accompanying table.

## RINGS OF SATURN

Date	$\Omega$	$i$	$N$	$J$	$\omega$
1920.0	168.3785	28.0893	127.2146	6.8403	42.3043
1921.0	.3925	.0892	.2555	.8358	.2760
1922.0	.4064	.0891	.2965	.8314	.2476
1923.0	.4203	.0889	.3375	.8270	.2192
1924.0	.4343	.0888	.3785	.8226	.1908
1925.0	168.4482	28.0887	127.4196	6.8181	42.1623
1926.0	.4621	.0885	.4607	.8137	.1337
1927.0	.4761	.0884	.5019	.8093	.1051
1928.0	.4900	.0883	.5431	.8049	.0765

1930.0	168.5179	28.0880	127.6256	6.7961	42.0191
1931.0	.5318	.0879	.6670	.7916	.41.9903
1932.0	.5458	.0878	.7084	.7872	.9615
1933.0	.5597	.0876	.7498	.7828	.9326
1934.0	.5736	.0875	.7913	.7784	.9037
1935.0	168.5876	28.0874	127.8328	6.7740	41.8747
1936.0	.6015	.0872	.8744	.7696	.8457
1937.0	.6155	.0871	.9160	.7652	.8167
1938.0	.6294	.0870	.9577	.7609	.7876
1939.0	.6433	.0869	127.9994	.7565	.7584
1940.0	168.6573	28.0867	128.0412	6.7521	41.7292
1941.0	.6712	.0866	.0830	.7477	.7000
1942.0	.6851	.0865	.1248	.7433	.6707
1943.0	.6991	.0863	.1667	.7389	.6414
1944.0	.7130	.0862	.2087	.7346	.6120
1945.0	168.7270	28.0861	128.2507	6.7302	41.5826
1946.0	.7409	.0859	.2927	.7258	.5532
1947.0	.7548	.0858	.3348	.7214	.5237
1948.0	.7688	.0857	.3769	.7171	.4941
1949.0	.7827	.0856	.4191	.7127	.4645
1950.0	168.7967	28.0854	128.4613	6.7084	41.4349

In forming  $U$ ,  $B$  and  $P$  the effect of nutation and planetary aberration is first removed from the apparent right ascension and declination of Saturn by subtracting from the right ascension

$(A - \tau) (m + n \sin a \tan \delta) + \frac{1}{18} B \cos a \tan \delta - 0.00577 \Delta \times \text{variation per day}$   
and from the declination

$(A - \tau) n \cos a - B \sin a - 0.00577 \Delta \times \text{variation per day}$

We have then

$$\begin{aligned}\cos B \sin P &= -\sin J \cos(a - N) \\ \cos B \cos P &= \cos J \cos \delta + \sin J \sin \delta \sin(a - N) \\ \sin B &= -\cos J \sin \delta + \sin J \cos \delta \sin(a - N) \\ \cos B \sin U &= \sin J \sin \delta + \cos J \cos \delta \sin(a - N) \\ \cos B \cos U &= \cos \delta \cos(a - N)\end{aligned}$$

Similarly, if  $l$  and  $b$  represent the heliocentric longitude and latitude of Saturn, referred to the mean equinox

$$\begin{aligned}\cos B' \sin P' &= -\sin i \cos(l - \Omega_0) \\ \cos B' \cos P' &= \cos i \cos b + \sin i \sin b \sin(l - \Omega_0) \\ \sin B' &= -\cos i \sin b + \sin i \cos b \sin(l - \Omega_0) \\ \cos B' \sin U' &= \sin i \sin b + \cos i \cos b \sin(l - \Omega_0) \\ \cos B' \cos U' &= \cos b \cos(l - \Omega_0)\end{aligned}$$

Müller's formula for the magnitude may be written

$$-8.68 + 5 \log r\Delta \pm 0.044(U' + \omega - U) - 2.60 \sin B + 1.25 \sin^2 B$$

where  $(U' + \omega - U)$  is measured in degrees and the sign of the third term is chosen to make this term positive.

#### *Satellites of Saturn* (Pages 625-635)

The data concerning the satellites of Saturn (except Rhea and Phoebe) are derived from the elements of H. Struve as given in *Observations de Poulkova*, Supplément I (St. Petersburg, 1888), in *Publications de l'Observatoire Central Nicolas*, Série II, Vol. XI (St. Petersburg, 1898), and in *Astronomische Nachrichten* 3885-86 (1903). The orbit of Rhea is given by G. Struve in *Veröffentlichungen der Universitäts-Sternwarte zu Berlin-Babelsberg*, Band VI, Heft 1, page 16. The differential co-ordinates of Phoebe are derived from elements and tables given by F. E. Ross in *Annals of the Harvard College Observatory*, Vol. 53, No. 6 (1905).

The times of elongation and conjunction have been corrected for light-time. The differential co-ordinates of Hyperion and Iapetus have not been thus corrected, so that light-time must be subtracted from the time of an observation before comparing with the ephemeris.

The symbols used on pages 632-635 have already been explained under *Satellites of Mars*.

Revised elements of the five inner satellites have been given by G. Struve in *Veröffentlichungen der Universitäts-Sternwarte zu Berlin-Babelsberg*, Band VI, Heft 4 (1930), and of Titan and Iapetus in Heft 5 (1933). These elements, together with those of H. Struve for Hyperion and of Ross for Phoebe, are given below. The notation used is:—

- $E_0$  = mean longitude at the epoch
- $n$  = tropical mean daily motion
- $t_s$  = number of days elapsed since the epoch
- $t$  = number of tropical years elapsed since the epoch
- $= t_s \div 365.2422$
- $\tau$  = date expressed in Besselian years
- $\delta l$  = libration in longitude
- $l_1, l$  = mean longitude in the orbit
- $\Theta_1$  = mean longitude of the ascending node on the ring-plane
- $\Omega$  = mean longitude of the ascending node on the ecliptic
- $i$  = inclination to the ecliptic
- $\gamma$  = inclination to the ring-plane
- $\Pi_1, \Pi$  = mean longitude of perisaturnium
- $e$  = eccentricity
- $a$  = semi-major axis at the mean distance of Saturn
- $A = a(\Delta)$  = semi-major axis at unit distance
- $\Delta$  = geocentric distance of Saturn
- $(\Delta)$  = mean distance of Saturn = 9.53887.

$l_1$ ,  $\Pi_1$  and  $\Theta_1$  are measured from the equinox in the ecliptic to the ascending node of the ring-plane on the ecliptic, then in the ring-plane, and then (except  $\Theta_1$ ) in the orbit itself.  $l$  and  $\Pi$  are measured from the equinox in the ecliptic to the ascending node of the orbit on the ecliptic, and then in the orbit itself. The ring-plane is assumed to be in the plane of Saturn's equator, and its node and inclination, as given on pages 832-833, are here denoted by  $\Omega_1$  and  $i_1$ .

For the five inner satellites

Epoch for  $E_0 = 1889$  April 0.0 G.M.T. = J.D. 241 1093.0

Epoch from which  $t$  is measured = 1889.25

*Mimas*

$$\begin{aligned} E_0 &= 127^\circ 05'.5 \\ n &= 381^\circ.99444 \ 2 \\ \delta l &= -44^\circ.390 \sin 5^\circ.0864(\tau - 1866.27) \\ &\quad - 0^\circ.764 \sin 3\{5^\circ.0864(\tau - 1866.27)\} \\ l_1 &= E_0 + nt_a + \delta l \\ \Theta_1 &= 56^\circ.1 - 365^\circ.23 \ t \\ \gamma &= 1^\circ 31'.0 \\ \Pi_1 &= 105^\circ.0 + 365^\circ.60 \ t \\ e &= 0.0201 \\ a &= 26''.826 \end{aligned}$$

 i &= 175^\circ.08 - 0^\circ.020 \ t & A &= 17861''
 \end{aligned}$$

For the six inner satellites  $L$ ,  $M$  and  $\theta$ , based on the elements of G. Struve, are tabulated on pages 840-841 at intervals of 10 days, the dates chosen being those on which the integral part of the Julian Day number is divisible by 10.

$L$  = mean longitude in the orbit, reckoned in the ring-plane from the ascending node of the ring-plane on the Earth's mean equator to the ascending node of the orbit on the ring-plane, and then in the orbit itself

$$= l_1 - \Omega_1 + \omega, \text{ where } \omega \text{ is defined on page 831}$$

$$= l - \Omega_1 + \omega - 2(\Omega - \Omega_1) \sin \frac{1}{2}i \sin \frac{1}{2}i_1$$

$M$  = mean anomaly  $= l_1 - \Pi_1 = l - \Pi$

$\theta$  = longitude of the ascending node of the orbit on the ring-plane, reckoned from the ascending node of the ring-plane on the Earth's mean equator

$$= \Theta_1 - \Omega_1 + \omega \text{ for Mimas, Enceladus, Tethys and Dione.}$$

For Rhea and Titan  $\epsilon$  and  $\sin \gamma$  are given also. In the case of Rhea  $\theta$  and  $\gamma$  are found from

$$\tan \eta = \frac{(\Omega - \Omega_1) \sin i_1}{i - i_1}$$

$$\theta = \eta + \omega + (\Omega - \Omega_1) \sin i_1 \cot i_1 (1 - \frac{1}{2} \sin^2 \eta)$$

$$\gamma = (\Omega - \Omega_1) \sin i_1 \operatorname{cosec} \eta$$

$$= (i - i_1) \sec \eta \text{ if } \operatorname{cosec} \eta \text{ is large.}$$

According to G. Struve: "As a consequence of perturbations by Titan, the longitude of the perisaturnium of Rhea is the same as that of Titan, oscillating about it in a period of 38 years. The eccentricity of the orbit of Rhea is a forced one, produced by Titan, and is subject to variations of corresponding period." Hence the term  $\Pi'$  in the elements of G. Struve has been replaced by the actual value of  $\Pi$  for Titan, but with the omission of the periodic solar perturbations.

For Titan the precessions of  $\Omega$  and  $i$  are assumed to be the same as those of  $\Omega_1$  and  $i_1$ ; this leads to

$$\Omega - \Omega_1 = -0^\circ.09545 + 0^\circ.65000 \sin(40^\circ.69 - 0^\circ.506 t)$$

$$i = 27^\circ.43883 + 0^\circ.30583 \cos(40^\circ.69 - 0^\circ.506 t) - 0^\circ.00013 t$$

where  $t$  is measured from 1890.0. Then

$$L = l - \Omega_1 + \omega - 2(\Omega - \Omega_1) \sin \frac{1}{2}i \sin \frac{1}{2}i_1$$

while  $\theta$ ,  $\eta$  and  $\sin \gamma$  are found from

$$\sin \gamma \sin(\theta - \omega) = \sin i \sin(\Omega - \Omega_1)$$

$$\sin \gamma \cos(\theta - \omega) = -\cos i \sin i_1 + \sin i \cos i_1 \cos(\Omega - \Omega_1)$$

$$\cos \gamma = \cos i \cos i_1 + \sin i \sin i_1 \cos(\Omega - \Omega_1)$$

$$\sin \gamma \sin \eta = \sin i_1 \sin(\Omega - \Omega_1)$$

$$\sin \gamma \cos \eta = \sin i \cos i_1 - \cos i \sin i_1 \cos(\Omega - \Omega_1)$$

As a check, since  $\Omega - \Omega_1$  and  $i - i_1$  are small,

$$\theta - \omega - \eta - (\Omega - \Omega_1) = -2(\Omega - \Omega_1) \sin \frac{1}{2}i \sin \frac{1}{2}i_1$$

Since  $g$  is strictly the distance of perisaturnium from the node of the satellite orbit on Saturn's orbit, the expression  $g = \Pi - \Omega - 4^\circ.5$  is replaced by

$$g = \Pi - \Omega - \Psi$$

where  $\Psi$  is the intercept on the orbit of the satellite from the node on the ecliptic

## EXPLANATION, 1935

## Mimas

$$u = L + 2^\circ.303 \sin M + 0^\circ.029 \sin 2M$$

$$\frac{r}{a} = 1.0002 - 0.0201 \cos M - 0.0002 \cos 2M$$

$$A = 255''.9 \quad \sin \gamma = 0.0265$$

## Enceladus

The motion of  $L$  in 10<sup>d</sup> varies from 2627°·315 to 2627°·306.

$$u = L + 0^\circ.509 \sin M$$

$$\frac{r}{a} = 1 - 0.0044 \cos M$$

$$A = 328''.3 \quad \sin \gamma = 0.0004$$

$$u - \theta = 117^\circ + 263^\circ.15 \text{ (J.D. - 242 8000.5)}$$

## Tethys

$$u = L \quad \frac{r}{a} = 1$$

$$A = 406''.4 \quad \sin \gamma = 0.0191$$

## Dione

$$u = L + 0^\circ.253 \sin M$$

$$\frac{r}{a} = 1 - 0.0022 \cos M$$

$$A = 520''.5 \quad \sin \gamma = 0.0004$$

$$u - \theta = 255^\circ + 131^\circ.62 \text{ (J.D. - 242 8000.5)}$$

<i>u</i> = <i>L</i> + 3°.323 sin <i>M</i> + 0°.060 sin 2 <i>M</i>	May 28-Aug. 23						
= <i>L</i> + 3°.322 sin <i>M</i> + 0°.060 sin 2 <i>M</i>	Aug. 24-Nov. 18						
= <i>L</i> + 3°.321 sin <i>M</i> + 0°.060 sin 2 <i>M</i>	Nov. 19-Dec. 34						
$\frac{r}{a} = 1.00042 - e \cos M - 0.00042 \cos 2M$	<i>A</i> = 1684°.4						
$x = \frac{A}{\Delta} \frac{r}{a} F \sin(u - U)$							
$y = \frac{A}{\Delta} \frac{r}{a} F \{ \sin B \cos(u - U) + \cos B \sin \gamma \sin(u - \theta) \}$							

The perturbations are given by

$$\Delta E = -3 \frac{n_0}{n} \{ e_0 \sin(l_0 - \Pi_0) + \frac{3}{4} e_0^2 \sin 2(l_0 - \Pi_0) \\ + \frac{1}{8} e^2 \sin 2(l_0 - \Pi) + \frac{3}{16} \sin^2 \Gamma \sin 2(l_0 - \Theta) \}$$

$$\Delta \Omega = \frac{3}{8} \frac{n_0}{n} \frac{\sin \Gamma}{\sin i} \sin(2l_0 - 2\Theta + \Psi)$$

$$\Delta i = \frac{3}{8} \frac{n_0}{n} \sin \Gamma \cos(2l_0 - 2\Theta + \Psi)$$

$$\Delta \Pi = \frac{1}{8} \frac{n_0}{n} \sin 2(l_0 - \Pi)$$

$$\Delta e = \frac{1}{8} \frac{n_0}{n} e \cos 2(l_0 - \Pi)$$

Converting these into perturbations of the quantities tabulated,

$$\Delta L = \Delta E - 2 \sin \frac{1}{2} i \sin \frac{1}{2} i_1 \Delta \Omega$$

$$\Delta M = \Delta E - \Delta \Pi$$

$$\sin \gamma \Delta \theta = \sin i \cos \eta \Delta \Omega - \sin \eta \Delta i$$

$$\Delta \gamma = \sin i \sin \eta \Delta \Omega + \cos \eta \Delta i$$

Hill's *Tables of Saturn* do not give the variation of the elements, so it is more convenient to use Le Verrier's elements, which are as follows.

$$\text{Epoch} = 1900 \text{ January } 1.0 \text{ G.M.T.} = \text{J.D. } 241\,5021.0$$

$$l_0 = 266^\circ.598 + 1223^\circ.510 T$$

$$\Omega_0 = 112^\circ.791 + 0^\circ.873 T$$

$$i_0 = 2^\circ.493 - 0^\circ.004 T$$

$$\Pi_0 = 91^\circ.098 + 1^\circ.958 T$$

$$e_0 = 0.055892 - 0.000345 T$$

where  $T$  is measured in Julian centuries of 36525 days.

The quantities  $\Theta$ ,  $\Gamma$  and  $\Psi$  are found from

$$\sin \Gamma \sin(\Theta - \Omega_0) = \sin i \sin(\Omega - \Omega_0)$$

$$\sin \Gamma \cos(\Theta - \Omega_0) = -\cos i \sin i_0 + \sin i \cos i_0 \cos(\Omega - \Omega_0) \\ \cos \Gamma = \cos i \cos i_0 + \sin i \sin i_0 \cos(\Omega - \Omega_0)$$

$$\sin \Gamma \sin \Psi = \sin i_0 \sin(\Omega - \Omega_0)$$

$$\sin \Gamma \cos \Psi = \sin i \cos i_0 - \cos i \sin i_0 \cos(\Omega - \Omega_0)$$

If, in order to cover the period 1927-1954, we put

$$\text{Epoch} = 1941 \text{ January } 6.0 \text{ G.M.T.} = \text{J.D. } 243\,0000.5$$

$j$  = number of days from epoch

$$A = l_0 - \Pi_0 = 316^\circ.48 + 0^\circ.033444 j$$

$$B = 2(l_0 - \Pi) = 211^\circ.48 + 0^\circ.064136 j$$

$$C = 2(l_0 - \Theta) = 111^\circ.03 + 0^\circ.066950 j$$

$$D = 2l_0 - 2\Theta + \Psi = 115^\circ.66 + 0^\circ.066950 j$$

$$a = \frac{3}{8} \frac{n_0}{n} 57.296 \sin \Gamma \cos \eta \operatorname{cosec} \gamma$$

$$b = -\frac{3}{8} \frac{n_0}{n} 57.296 \sin \Gamma \sin \eta \operatorname{cosec} \gamma$$

$$c = \frac{3}{8} \frac{n_0}{n} \sin \Gamma \sin \eta$$

$$d = \frac{3}{8} \frac{n_0}{n} \sin \Gamma \cos \eta$$

then

$$\Delta E = -0^{\circ}01422 \sin A - 0^{\circ}00059 \sin 2A - 0^{\circ}00020 \sin B \\ - 0^{\circ}00945 \sin C$$

$$\Delta \Omega = +0^{\circ}03046 \sin D$$

$$\Delta i = +0^{\circ}01417 \cos D$$

$$\Delta \Pi = +0^{\circ}1594 \sin B$$

$$\Delta e = +0.00008 \, 06 \cos B$$

$$\Delta L = \Delta E - 0^{\circ}00354 \sin D$$

$$\Delta M = \Delta E - \Delta \Pi$$

$$\Delta \theta = a \sin D + b \cos D \quad \text{in degrees}$$

$$\Delta(\sin \gamma) = c \sin D + d \cos D$$

The values of  $a$ ,  $b$ ,  $c$  and  $d$ , at intervals of 1000 days, are given in the table below,  $c$  and  $d$  being in units of the 7th decimal.

Date	J.D.	$a$	$b$	$c$	$d$

1938 Apr. 12.0	242 9000.5	2.222	.251	278	2458
1941 Jan. 6.0	243 0000.5	2.243	.210	231	2463
1943 Oct. 3.0	243 1000.5	2.262	.168	183	2467
1946 June 29.0	243 2000.5	-2.279	-0.123	+134	-2470

The true longitude  $u$  in the orbit, reckoned in the same way as  $L$ , and the ratio of the radius vector  $r$  to the semi-major axis  $a$ , are found from

$$u = L + (v - M) \\ v - M = 57^{\circ}2958 (2e \sin M + 1.25 e^2 \sin 2M) \\ \frac{r}{a} = 1 + \frac{1}{2}e^2 - e \cos M - \frac{1}{2}e^2 \cos 2M$$

The rectangular co-ordinates of a satellite, measured in seconds of arc and referred to axes through the centre of Saturn, the axis of  $x$  being in the ring-plane and positive towards the east, and the axis of  $y$  being directed positively towards the north pole of Saturn, are

$$x = \frac{A}{\Delta} \frac{r}{a} F \sin(u - U) \\ y = \frac{A}{\Delta} \frac{r}{a} F \{ \sin B \cos(u - U) + \cos B \sin \gamma \sin(u - \theta) \}$$

in which the second term in  $y$  can often be neglected, and where

$$F = \frac{\Delta}{\Delta + r \cos(u - U)}$$

in which  $\Delta$  may usually be given its mean value of 9.53887, and  $r$  taken as  $a$ , so that  $F$  may be tabulated for each satellite with argument  $u - U$ .  $F$  is identical with

the quantity called  $\frac{1}{1 + \xi}$  by Marth and Struve.

The distance  $s$  of the satellite from the centre of Saturn, and its position angle  $p$ , may be found from

$$s \sin(p - P) = x$$

$$s \cos(p - P) = y$$

The differences of right ascension and declination, in the sense satellite *minus* Saturn, are

$$\Delta\alpha = \frac{1}{r} s \sin p \sec(\delta + \Delta\delta)$$

$$\Delta\delta = s \cos(p + \frac{1}{2}\Delta\alpha \sin \delta)$$

$$= s \cos p - \frac{2\Delta\alpha^2}{4} \sin 2\delta \sin r''$$

in which the second term in  $\Delta\delta$  may be neglected.

In the above no allowance is made for light-time, which must be added to the computed time of any phenomenon, or subtracted from the observed time. The light-time is strictly  $498^s.58$   $FA$ , but may be taken as

$$\text{Light-time} = 498^s.6 \Delta = 8^m.310 \Delta = 0^d.005771 \Delta$$

The values of  $\frac{1}{\Delta}$  and the light-time are tabulated on pages 838–839.

#### *Satellites of Uranus and Neptune* (Pages 636–639)

The data concerning Ariel and Umbriel, the inner satellites of Uranus, are derived from elements given by Newcomb in *Uranian and Neptunian Systems, Washington Observations*, 1873, Appendix I. The data concerning Titania and Oberon, the outer satellites of Uranus, are derived from elements given by H. Struve in *Abhandlungen der Königlich Preussischen Akademie der Wissenschaften*, 1912.

The data concerning the satellite of Neptune are derived from elements given by Eichelberger and Newton in *The Orbit of Neptune's Satellite and the Pole of Neptune's Equator*, in *Astronomical Papers of the American Ephemeris*, Vol. IX, Part III.

The symbols used are explained under *Satellites of Mars*.

#### *Magnitudes of Uranus and Neptune*

These may be found from Müller's formulæ:—

$$\text{For Uranus } m = -6.85 + 5 \log r\Delta$$

$$\text{For Neptune } m = -7.05 + 5 \log r\Delta$$

On account of the small variation of  $r$  the formulæ may be simplified:—

$$\text{For Uranus } m = m_0 + 5 \log \Delta$$

$$\text{For Neptune } m = +0.35 + 5 \log \Delta$$

where  $m_0$  has the following values:—

1931	−0.35	1934	−0.36	1937	−0.38
1932	−0.35	1935	−0.37	1938	−0.38
1933	−0.36	1936	−0.37	1939	−0.39

The magnitudes at opposition in 1935 are

Uranus 6.0                      Neptune 7.7

#### *Phenomena* (Pages 640–641)

The symbols used are defined on page 750, although the majority will be found on the lower half of page 641.

The times of equinoxes and solstices are those at which the Sun's apparent longitude is a multiple of  $90^\circ$ . The dates of perihelion and aphelion are those on which the radius vector of the Sun is a minimum and maximum respectively. On

account of perturbations they are not always the same as the dates on which the longitude of the Sun is equal to the mean longitude of perigee or apogee given on page 54.

For solar eclipses the time of conjunction in right ascension is given, and for lunar eclipses the time of mid-eclipse.

The dates of greatest brilliancy of Venus are those on which the expression

$$\frac{(r + \Delta + R)(r + \Delta - R)}{r^3 \Delta^3}$$

is a maximum,  $r$  and  $R$  being the radii vectores of Venus and the Earth respectively, and  $\Delta$  the geocentric distance of Venus.

The dates of conjunction with or opposition to the Sun are those on which the differences of apparent geocentric longitude are  $0^\circ$  and  $180^\circ$  respectively. The dates when the planets are stationary are those on which they are stationary in right ascension. Similarly the dates of elongation are those on which the differences of geocentric longitude are a maximum, no account being taken of the latitude of the planet concerned.

The times of conjunction of planets with the Moon or with one another are those at which the two bodies have the same right ascension, and in general, differ slightly from the times of closest approach. The conjunctions of planets with the Moon are omitted if the difference of declination is greater than  $7^\circ$ , and also, in the case of Uranus and Neptune, if the conjunction occurs within 48 hours of New Moon. The conjunctions of planets in pairs are omitted if the difference of declination is greater than  $3^\circ$ . Conjunctions of planets with first magnitude stars are given when the difference of declination at conjunction does not exceed  $10'$ .

#### *Sunrise and Sunset (Pages 642-663)*

This table enables the time of sunrise or sunset at any place between the equator and latitude  $+60^\circ$  to be obtained immediately. The times given may be regarded as local mean times of sunrise or sunset, although strictly they are the Greenwich mean times of sunrise or sunset for places on the meridian of Greenwich, and an interpolation for longitude (yielding a maximum correction of  $1^m$ ) is theoretically necessary in order to give the local mean time for a place not on the meridian of Greenwich.

At the times given the true zenith distance of the Sun's centre is  $90^\circ 50', 34'$  having been allowed for horizontal refraction and  $16'$  for semi-diameter. The beginning of morning twilight and end of evening twilight are the instants when the true zenith distance of the Sun's centre is  $108^\circ$ .

In order to avoid the necessity for a special table for southern latitudes, the time of sunrise or sunset at a southern station is found by taking the time of the same phenomenon at a northern station at the same distance from the equator on the day (about six months earlier or later) when the Sun's declination is opposite in sign but as nearly as possible equal in numerical value. To the time thus found must be applied a correction equal to the difference between the values of the equation of time on the two dates concerned. The required dates and corrections are tabulated on pages 662-663.

#### *Moonrise and Moonset (Pages 664-681)*

At the times given the true geocentric zenith distance of the Moon's centre is  $90^\circ 50'$  minus the Moon's horizontal parallax. Here, as in the case of the Sun,  $34'$  has been allowed for horizontal refraction and  $16'$  for semi-diameter.

A special table for southern latitudes is avoided by making use of the fact that, if there were no refraction or parallax, the time of rising or setting of the Moon's centre at any place would be exactly the same as the time of setting or rising at a point on the Earth diametrically opposite this place. The corrections required to allow for refraction, semi-diameter and parallax are equal in magnitude for the two places but opposite in sign. As the correction has already been applied in the case of northern stations, it must be doubled and applied with the opposite sign in order to give correct times for southern stations; it is computed by means of the table on page 680.

The hour angle of the Moon is given by

$$\cos h = -\tan \phi \tan \delta + \cos z \sec \phi \sec \delta$$

where  $z$  is the zenith distance. Here  $z = 90^\circ 50' - \pi$ , and does not differ from  $90^\circ$  by more than  $11'$ . Hence the hour angle when  $z = 90^\circ$  must be corrected by

$$\begin{aligned} & \pm \frac{\sec \phi \sec \delta \sin(\pi - 50') \operatorname{cosec} 1^m}{\sqrt{1 - \tan^2 \phi \tan^2 \delta}} \\ & = \pm \frac{\sqrt{2} \sin(\pi - 50') \operatorname{cosec} 1^m}{\sqrt{\cos 2\phi + \cos 2\delta}} \end{aligned}$$

in minutes of sidereal time. This correction must be reduced to minutes of mean time, and allowance made for the average hourly motion of the Moon in right ascension, which may be taken as  $132^s$ . Thus the factor on page 680 is

$$\pm \frac{2 \times \sqrt{2} \times 3610}{15 (3610 - 132) \sqrt{\cos 2\phi + \cos 2\delta}} = \pm \frac{0.196}{\sqrt{\cos 2\phi + \cos 2\delta}}$$

The rule for signs follows immediately from the consideration that the geocentric zenith distance of the Moon's centre at the times given is always less than  $90^\circ$ .

#### *Observatories (Pages 682-703)*

Three separate lists of observatories are given,

*List A.—Active Observatories.*—The positions given are based on replies sent by the various observatories to letters asking for their geographical co-ordinates. Six observatories have been added to this list since 1934, namely Cape of Good Hope, Kitab, Lake Angelus, Morwenstow, Muswell Hill and Oak Ridge. Revised data are given for Bogota, Leiston and Stockholm. Frome and Pennant Hills have been transferred to List B.

In the quantities  $\rho \sin \phi'$ ,  $\rho \cos \phi'$ , etc. the effect of altitude has been included in every case where it is known. The formulæ and tables used are given on pages 726 and 727, in Tables X and XI.

*List B.—Former Observatories.*—This list includes not only observatories that have ceased to exist or be active, but also former positions of active observatories in List A. In general only observatories of historical importance have been included. Certain omissions are due to the difficulty of obtaining the necessary data. Frome, Lund, Pennant Hills and Stockholm have been added to the list since 1934.

*List C.—Index List.*—Lists A and B are given in alphabetical geographical order. As many observatories are better known by special names, or by the name of the individual or institution to which they belong, List C provides a means of locating them in one of the other lists. Names of towns or suburban or country locations sometimes associated with observatories are included. References are also given in this list to all branch observatories.

The authority for the spelling of all geographical names is the leaflets published for the Permanent Committee on Geographical Names by the Royal Geographical Society, Kensington Gore, London, S.W.7.

Every effort is made to keep this list of observatories up to date. Directors and others concerned are requested to communicate corrections or additions.

*Standard Times (Pages 704-713)*

These pages show the standard times adopted in various countries. They also indicate the difference between the standard time of any country and Greenwich mean time in the sense Greenwich mean time *minus* standard time. As changes are liable to occur in this list users should consult the latest *Nautical Almanac* available.

In many countries the legal time is advanced during a portion of the year, and this advanced time is commonly known as *Summer Time*. In the British Isles this practice began in 1916, and was stabilised by the *Summer Time Act, 1925*, which enacted that

(1) The time for general purposes in Great Britain shall, during the period of summer time, be one hour in advance of Greenwich mean time.

(2) Wherever any reference to a point of time occurs in any enactment, Order in Council, order, regulation, rule, byelaw, deed, notice or other document whatsoever, the time referred to shall, during the period of summer time, be deemed, subject as hereinafter provided, to be the time as fixed for general purposes by this Act.

(3) Nothing in this Act shall affect the use of Greenwich mean time for purposes of astronomy, meteorology, or navigation, or affect the construction of any document mentioning or referring to a point of time in connection with any of those purposes.

(4) For the purposes of this Act, the period of summer time shall be taken to be the period beginning at two o'clock, Greenwich mean time, in the morning of the day next following the third Saturday in April, or, if that day is Easter Day, the day next following the second Saturday in April, and ending at two o'clock, Greenwich mean time, in the morning of the day next following the first Saturday in October.

The duration of Summer Time is given below for the years 1916 to 1939. The dates for the years 1916 to 1924 do not conform to the rule now in force.

Year	Duration	Year	Duration
1916	May 21 to October 1	1928	April 22 to October 7
1917	April 8 to September 17	1929	April 21 to October 6
1918	March 24 to September 30	1930	April 13 to October 5
1919	March 30 to September 29	1931	April 19 to October 4
1920	March 28 to October 25	1932	April 17 to October 2
1921	April 3 to October 3	1933	April 9 to October 8
1922	March 26 to October 8	1934	April 22 to October 7
1923	April 22 to September 16	1935	April 14 to October 6
1924	April 13 to September 21	1936	April 19 to October 4
1925	April 19 to October 4	1937	April 18 to October 3
1926	April 18 to October 3	1938	April 10 to October 2
1927	April 10 to October 2	1939	April 16 to October 8

*Tables I and II (Pages 714-717)*

These tables enable the *Julian Day Number* of any day up to the year 2000 to be found. When a decimal is used with a Julian Day Number it is understood that the day commences at Greenwich mean noon.

*Tables III and IV (Pages 718-719)*

These tables are used for converting intervals of mean solar time into intervals of *uniform* sidereal time (see page 774) and vice versa. They are based on the following conversion ratios derived from Newcomb's value of the tropical year:—

1 mean solar day = 1.00273 79093 uniform sidereal days  
= 24<sup>h</sup> 03<sup>m</sup> 56<sup>s</sup>.55536 in uniform sidereal time

1 uniform sidereal day = 0.99726 95664 mean solar days  
= 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>.09054 in mean solar time.

When three decimals of a second are retained, as in the most refined modern time-keeping, these tables are used for connecting mean solar and uniform sidereal times. When keeping time to 0<sup>s</sup>.01 only, the tables are used in the manner illustrated for connecting mean solar and true sidereal times.

*Tables V-IX (Pages 720-725)*

These conversion tables do not require explanation. Decimals of a day may be converted to hours, minutes and seconds by the inverse use of Table IX.

*Tables X and XI (Pages 726-727)*

These tables are based on a compression  $c$  of  $\frac{1}{297.0}$ . The series on which they are based, together with the series for  $\rho$ , the ratio of the radius to the equatorial radius, are given below, with terms up to  $c^3$ .

$$S = \frac{\rho \sin \phi'}{\sin \phi} = 1 - \frac{3}{2}c + \frac{5}{16}c^2 + \frac{3}{32}c^3 - \left(\frac{1}{2}c - \frac{1}{2}c^2 - \frac{5}{64}c^3\right) \cos 2\phi$$

$$+ \left(\frac{3}{16}c^2 - \frac{3}{32}c^3\right) \cos 4\phi - \frac{5}{64}c^3 \cos 6\phi$$

$$C = \frac{\rho \cos \phi'}{\cos \phi} = 1 + \frac{1}{2}c + \frac{5}{16}c^2 + \frac{7}{32}c^3 - \left(\frac{1}{2}c + \frac{1}{2}c^2 + \frac{27}{64}c^3\right) \cos 2\phi$$

$$+ \left(\frac{3}{16}c^2 + \frac{9}{32}c^3\right) \cos 4\phi - \frac{5}{64}c^3 \cos 6\phi$$

$$\rho = 1 - \frac{1}{2}c + \frac{5}{16}c^2 + \frac{5}{32}c^3 + \left(\frac{1}{2}c - \frac{13}{64}c^3\right) \cos 2\phi$$

$$- \left(\frac{5}{16}c^2 + \frac{5}{32}c^3\right) \cos 4\phi + \frac{13}{64}c^3 \cos 6\phi$$

These reduce to

$$S = 0.9949\ 5304 - 0.0016\ 7783 \cos 2\phi + 0.0000\ 0212 \cos 4\phi$$

$$C = 1.0016\ 8705 - 0.0016\ 8919 \cos 2\phi + 0.0000\ 0214 \cos 4\phi$$

$$\rho = 0.9983\ 2005 + 0.0016\ 8349 \cos 2\phi - 0.0000\ 0355 \cos 4\phi + 0.0000\ 0001 \cos 6\phi$$

*Table XII (Pages 728-729)*

This table enables approximate precessions to 0<sup>s</sup>.01 and 0<sup>s</sup>.1 for declinations less than  $\pm 60^\circ$  to be found at sight.

*Tables XIII and XIV (Pages 730-734)*

These tables are for the rigorous reduction of star positions from the equinox of the beginning of the year to that of 1950.0, and will be useful in cases where accurate precessions and secular variations are not known. They have the advantage of involving functions of the right ascension and declination at the initial epoch only, and not at the mid-epoch. They are based on Ristenpart's formulæ:—

$$\begin{aligned} a &= a_0 + \zeta_0 & A &= \zeta_0 + z + \frac{\sin^2 \theta \sin 2a}{60 \sin 1''} \\ A_1 &= \frac{\sin \theta \sin a}{15 \sin 1''} & A_2 &= \frac{\sin^2 \theta \sin 2a}{30 \sin 1''} \\ D &= \frac{\sin \theta \cos a}{\sin 1''} & D_1 &= -\frac{\sin^2 \theta \sin^2 a}{2 \sin 1''} \end{aligned}$$

where  $A$ ,  $A_1$  and  $A_2$  are measured in time, and  $D$  and  $D_1$  in arc.

These reduce, for working purposes, to

$$\begin{aligned} A &= \zeta_0 + z + \frac{1}{2}A_2 = M + \frac{1}{2}A_2 \\ p &= \frac{\sin \theta \cos \zeta_0}{15 \sin 1''} & q &= \frac{\sin \theta \sin \zeta_0}{15 \sin 1''} \\ A_1 &= p \sin a + q \cos a \\ A_2 &= 0.0000048481 A_1 D \\ D &= -15 \times \text{value of } A_1 \text{ for } (a - 6^h) \\ D_1 &= -0.00054542 A_1^2 \end{aligned}$$

For stars near the pole the formulæ on page 787 may be used.

*Table XV (Page 735)*

This table is intended to facilitate the approximate reduction of ephemerides of comets and minor planets from the standard equinox of 1950.0 to the true equinox of date. The dates are those adopted in 1928 at the Leiden meeting of the International Astronomical Union in the following resolution: "That the dates used in giving the osculation epochs of elements for comets and minor planets shall be the midnight following an integral Julian date that is exactly divisible by 40, and, for ephemerides, divisible by 8 (or 4 etc.)." The dates marked with an asterisk are the osculation dates.

The formulæ for  $f$ ,  $g$  and  $G$  are

$$f = M + f_0$$

$M$  being given on page 54, and being the reduction to the beginning of the year, and  $f_0$  being here the independent day number  $f$  given on pages 274-288.

$$g \sin G_0 = \frac{1}{60} B$$

$$g \cos G_0 = N' + n'A$$

$$G = G_0 - 15.5(1950 - 1935)$$

$N'$  and  $n'$  being the values of  $N''$  and  $n''$  on page 54 reduced to minutes of arc.  $n'$  may be taken as  $\frac{1}{2}$ , and since  $g \sin G_0$  is very small in comparison with  $g \cos G_0$

$$g = -g \cos G_0 - \frac{(g \sin G_0)^2}{2g \cos G_0}$$

The quantities  $j$  and  $J$  on page 294 are related to the quantities  $g$  and  $G$  as follows:—

$$j = 60 g \sin 1^m = 0.262 g \qquad J = G - 6^h$$

*Tables XVI and XVIIA (Pages 736–741)*

Table XVI gives the azimuth of *Polaris* at all hour angles for latitudes from  $10^\circ$  to  $70^\circ$ , on the assumption that the declination of *Polaris* is  $88^\circ 57' 35''$ . It is computed from

$$\tan A = \frac{\sin h \cot \delta \sec \phi}{1 - \cos h \cot \delta \tan \phi}$$

The necessary correction is

$$\begin{aligned} \Delta A &= - \frac{A (\delta - 88^\circ 57' 35'')}{(90^\circ - 88^\circ 57' 35'')} \\ &= -0.000263 A (\delta - 88^\circ 57' 35'') \end{aligned}$$

where  $\delta - 88^\circ 57' 35''$  is in seconds of arc. This correction is tabulated in Table XVIIA. It may be remarked that the above differential formula assumes the zenith distance of *Polaris* to be the same as the colatitude.

*Tables XVII–XXI (Pages 742–749)*

These tables have been included to facilitate interpolation of the quantities in the *Nautical Almanac*. The notation commonly employed in astronomical usage is

Function	Differences				
	First	Second	Third	Fourth	Fifth
$f_{-2}$	$\Delta'_{-2}$				
$f_{-1}$	$\Delta'_{-1}$	$\Delta''_{-1}$			
$f_0$	$\Delta'_0$	$\Delta''_0$	$\Delta'''_0$	$\Delta^{iv}_0$	
	$\Delta'_1$		$\Delta'''_1$		$\Delta^v_1$
$f_1$	$\Delta'_1$	$\Delta''_1$		$\Delta^{iv}_1$	
	$\Delta'_2$		$\Delta'''_2$		
$f_2$	$\Delta'_2$	$\Delta''_2$			
$f_3$					

which, for our present purposes, may be simplified thus:—

Function	Differences				
$f_0$		$\Delta''_0$		$\Delta^{iv}_0$	
	$\Delta'$		$\Delta'''$		$\Delta^v$
$f_1$		$\Delta''_1$		$\Delta^{iv}_1$	

If differences are available either Bessel's or a modified Everett formula may be used. Bessel's formula may be written\*

$$f_n = f_0 + n\Delta' + B''(\Delta''_0 + \Delta''_1) + B''' \Delta''' + B^{iv}(\Delta^{iv}_0 + \Delta^{iv}_1)$$

\* The definitions of  $B''$  and  $B^{iv}$  here adopted differ by a factor  $\frac{1}{2}$  from those in the *Nautical Almanac* for 1931–34; the change enables double differences to be used instead of mean differences.

where  $n$  is the fraction of the interval between two tabular values, and

$$B'' = \frac{n(n-1)}{2 \cdot 2!}$$

$$B''' = \frac{n(n-1)(n-\frac{1}{2})}{3!}$$

$$B^{iv} = \frac{(n+1)n(n-1)(n-2)}{2 \cdot 4!}$$

$$\Delta_0'' + \Delta_1'' = \Delta_{\frac{1}{2}}' - \Delta_{-\frac{1}{2}}'$$

$$\Delta_0^{iv} + \Delta_1^{iv} = \Delta_{\frac{1}{2}}''' - \Delta_{-\frac{1}{2}}'''$$

The modified Everett formula is

$$f_n = f_0 + n\Delta' + E_0''\Delta_0'' + E_1''\Delta_1'' + B^{iv}(\Delta_0^{iv} + \Delta_1^{iv})$$

in which  $f_0 + n\Delta'$  may be replaced by  $(1-n)f_0 + nf_1$  and where

$$E_0'' = -\frac{n(n-1)(n-2)}{6}$$

$$E_1'' = \frac{(n+1)n(n-1)}{6}$$

The use of four terms of Everett's formula is exactly equivalent to the use of four terms of Bessel's formula, in other words it includes the effect of third differences

It will be observed that

$$B^{iv} = \frac{B''(n+1)(n-2)}{12}$$

The quantity  $\frac{(n+1)(n-2)}{12}$  varies over a small range as  $n$  varies from 0 to 1. If a constant value  $-0.184$  be assigned to it, and if we write

$$M'' = \Delta'' - 0.184 \Delta^{iv}$$

Bessel's formula becomes

$$f_n = f_0 + n\Delta' + B''(M_0'' + M_1'') + B''\Delta''$$

the error of which is less than half a unit of the last decimal if the fourth difference does not exceed 1000. Similarly Everett's formula may be written

$$f_n = f_0 + n\Delta' + E_0''M_0'' + E_1''M_1''$$

This method, known as the throw-back, enables the effect of a small fourth difference to be taken into account very easily, as Table XXI gives values of  $0.184 \Delta^{iv}$  with argument  $\Delta^{iv}$ . The same principle\* can also be applied to higher order differences, for instance  $M''' = \Delta''' - \frac{1}{6}\Delta^{iv}$  can be used up to  $\Delta^{iv} = 5000$ .

The number of differences to be used in any particular problem must be determined by the computer, it is governed by the simple condition that the effect of the neglected differences must be negligible in comparison with the working unit. The maximum effect of second differences, attained when  $n = \frac{1}{2}$ , is  $\frac{1}{8}\Delta''$  or  $\frac{1}{16}(\Delta_0'' + \Delta_1'')$ , so that second differences may be considered negligible if the double second difference, i.e.  $\Delta_0'' + \Delta_1''$ , is less than 8. The maximum value of  $B''$  is 0.008, so that third differences less than about 60 may be neglected. Similarly, since the maximum value of  $B^{iv}$ , attained when  $n = \frac{1}{2}$ , is 0.012, fourth differences are negligible if the double fourth difference  $\Delta_0^{iv} + \Delta_1^{iv}$  does not exceed 40.

\* See "On the Construction of Tables by Interpolation." *M.N.R.A.S.*, 83, 1913, p. 111; *Nautical Almanac*, 1931, 831, and *British Association Mathematical Tables*, 1928, p. 111.

average fourth difference does not exceed 20. The effect of fifth differences is always negligible when interpolating quantities in the *Nautical Almanac*; the maximum value of the Besselian coefficient of the fifth difference is less than 0.001.

The choice of formula is often a matter of individual preference, but the following remarks may be found helpful. If the fourth and higher order differences are negligible, Everett's formula has the advantage of avoiding the necessity for finding the third difference—as, for instance, in the Sun's co-ordinates  $X, Y, Z$ , where second differences are printed and fourth differences are always negligible. When fourth differences must be included, either formula may be used, either with the term  $B''(\Delta_0'' + \Delta_1'')$ , or with the throw-back.

Interpolation may be performed without differences. Thus linear interpolation becomes

$$f_n = (1 - n)f_0 + nf_1$$

while interpolation that includes differences up to the third may be done by the 4-point Lagrange formula

$$f_n = L_{-1}f_{-1} + L_0f_0 + L_1f_1 + L_2f_2$$

where

$$L_{-1} = -\frac{n(n-1)(n-2)}{6} = E_0''$$

$$L_0 = \frac{(n+1)(n-1)(n-2)}{2}$$

$$L_1 = -\frac{(n+1)n(n-2)}{2}$$

$$L_2 = \frac{(n+1)n(n-1)}{6} = E_1''$$

$$L_{-1} + L_0 + L_1 + L_2 = 1$$

This formula may also replace the first four terms of Bessel's or Everett's formula, the effect of fourth differences, if appreciable, being applied in the usual way, i.e. by  $+B''(\Delta_0'' + \Delta_1'')$ . It has been found that cases arise where it is convenient to use Lagrangian formulæ, especially when a calculating machine is being used. The case where  $n = \frac{1}{2}$ , i.e. when the interval of a table is being halved, reduces to the very simple form

$$f_{\frac{1}{2}} = 0.0625(-f_{-1} + 9f_0 + 9f_1 - f_2)$$

or, if it is necessary to include differences up to the fifth,

$$f_{\frac{1}{2}} = \frac{1}{256}(3f_{-2} - 25f_{-1} + 150f_0 + 150f_1 - 25f_2 + 3f_3)$$

Table XVII is a critical table giving 4-decimal values of  $B''$ , to be used when  $\Delta_0'' + \Delta_1''$  is greater than 1000 but less than 10,000. Table XVIII is a similar 3-decimal table, which suffices when  $\Delta_0'' + \Delta_1''$  is less than 1000, since the maximum error of a value taken from a critical table is only half a unit in the last decimal, whereas in ordinary tables where interpolation is required it may amount to a unit.

Table XIX contains 5-decimal values of the second-difference Everett and the 4-point Lagrange coefficients at interval 0.01. The tabulated coefficients would be exact if carried to seven decimals, but the rounding-off in  $L_{-1}$  is equal and opposite to that of  $L_2$ , and similarly for  $L_0$  and  $L_1$ . Thus for  $n = 0.23$

$$L_{-1} = -0.05224 \ 45$$

$$L_2 = -0.03630 \ 55$$

$$L_0 = +0.83818 \ 35$$

$$L_1 = +0.25036 \ 65$$

On account of this peculiar property the tabulated 5-decimal values may frequently be used for the interpolation of 6- and even 7-figure numbers, if interpolating to exact hundredths. Everett coefficients at interval 0.001 are given in Thompson's *Table of the Coefficients of Everett's Central-Difference Formula* (Cambridge University Press).

Table XIX also gives critical tables of  $B''$  and  $B'''$ . If  $\Delta''$  is greater than 1000 the table of  $B''$  should not be used, but the Everett formula and the 5-decimal values of  $E_0''$  and  $E_1''$ .

Table XX is a critical table giving 3-decimal values of the second-difference Everett coefficients, and may be used when the second difference does not exceed 1000.

Table XXI gives values of 0.184  $\Delta''$ , with argument  $\Delta''$ , for use with the throw-back from fourth to second differences.

The following examples illustrate the use of the formulæ and tables given. Although the full details of each are given, a computer using a calculating machine would accumulate the products on the machine, writing nothing but the interpolate.

*Example 1.*—To find  $y$  when  $x = 1.2789$ .

$x$	$y$	$\Delta'$	$\Delta''$	$\Delta'''$
1.1	+0.8912			
		+408		
1.2	.9320		-92	
		+316		-6
1.3	.9636		-98	
		+218		
1.4	+0.9854			

Using Bessel's formula and Table XVIII,

$$\begin{aligned}
 f_0 &= y \text{ for } x = 1.2 &= +0.9320 \\
 n\Delta' &= +0.789 \times +316 &= +2493 \\
 B''(\Delta_0'' + \Delta_1'') &= -0.042 \times -190 &= +80 \\
 \text{Sum} &= f_n &= +0.9577
 \end{aligned}$$

Note that  $\Delta_0'' + \Delta_1'' = -92 - 98$  or  $+218 - 408 = -190$ , the latter form being convenient when first differences only are printed.

*Example 2.*—To find  $y$  when  $x = 1.2345$ .

$x$	$y$	$\Delta'$	$\Delta''$	$\Delta'''$	$\Delta''''$
1.0	+0.54030				
		-8670			
1.1	.45360		-454		
		-9124		+92	
1.2	.36236		-362		+3
		-9486		+95	
1.3	.26750		-267		+1
		-9753		+96	
1.4	.16997		-171		
		-9924			
1.5	+0.07073				

Using Bessel's formula and Tables XVIII and XIX,

$$\begin{aligned} f_0 &= y \text{ for } x = 1.2 &= +0.36236 \\ n\Delta' &= +0.345 \times -9486 &= -32727 \\ B''(\Delta_0'' + \Delta_1'') &= -0.056 \times -629 &= +352 \\ B'''\Delta''' &= +0.006 \times +95 &= +6 \\ \text{Sum} &= f_n &= +0.32999 \end{aligned}$$

Using Everett's formula and Table XX,

$$\begin{aligned} f_0 &= y \text{ for } x = 1.2 &= +0.36236 \\ n\Delta' &= +0.345 \times -9486 &= -32727 \\ E_0''\Delta_0'' &= -0.062 \times -362 &= +224 \\ E_1''\Delta_1'' &= -0.051 \times -267 &= +136 \\ \text{Sum} &= f_n &= +0.32999 \end{aligned}$$

Using the Lagrange formula and Table XIX,

$$\begin{aligned} L_{-1}f_{-1} &= -0.06233 \times +0.45360 &= -0.028273 \\ L_0f_0 &= +0.72901 \times +0.36236 &= +0.264164 \\ L_1f_1 &= +0.38398 \times +0.26750 &= +0.102715 \\ L_2f_2 &= -0.05066 \times +0.16997 &= -0.008611 \\ \text{Sum} &= f_n &= +0.32999 \end{aligned}$$

Example 3.—To find  $y$  when  $x = 0.24680$ .

$x$	$y$	$\Delta'$	$\Delta''$	$\Delta'''$	$\Delta^{iv}$
0.0	+1.00000				
		-4865			
0.1	0.95135		+1547		
		-3318		-299	
0.2	.91817		+1248		+100
		-2070		-199	
0.3	.89747		+1049		+68
		-1021		-131	
0.4	.88726		+918		
		-103			
0.5	+0.88623				

Using Bessel's formula and Tables XVII and XIX,

$$\begin{aligned} f_0 &= y \text{ for } x = 0.2 &= +0.91817 \\ n\Delta' &= +0.4680 \times -2070 &= -9688 \\ B''(\Delta_0'' + \Delta_1'') &= -0.0622 \times +2297 &= -1429 \\ B'''\Delta''' &= +0.001 \times -199 &= -2 \\ B^{iv}(\Delta_0^{iv} + \Delta_1^{iv}) &= +0.012 \times +168 &= +20 \\ \text{Sum} &= f_n &= +0.90707 \end{aligned}$$

Using the modified Everett formula and Table XIX,

$$\begin{aligned} f_0 &= y \text{ for } x = 0.2 &= +0.91817 \\ n\Delta' &= +0.4680 \times -2070 &= -9688 \\ E_0''\Delta_0'' &= -0.0636 \times +1248 &= -794 \\ E_1''\Delta_1'' &= -0.0609 \times +1049 &= -639 \\ B^{iv}(\Delta_0^{iv} + \Delta_1^{iv}) &= +0.012 \times +168 &= +20 \\ \text{Sum} &= f_n &= +0.90707 \end{aligned}$$

Using Bessel's formula with Tables XVII and XIX and the throw-back with Table XXI,

$$M_0'' + M_1'' = +2297 - 31 = +2266$$

$$f_0 = y \text{ for } x = 0.2 = +0.91817$$

$$n\Delta' = +0.4680 \times -2070 = -9688$$

$$B''(M_0'' + M_1'') = -0.0622 \times +2266 = -1409$$

$$B''\Delta'' = +0.001 \times -199 = -2$$

$$\text{Sum} = f_n = +0.90707$$

The use of the throw-back enables tables to be published in compressed form. Thus from the two lines

$x$	$y$	$M''$
0.2	+0.91817	+1230
0.3	+0.89747	+1036

and Everett's formula in the form

$$f_n = (1 - n)f_0 + nf_1 + E_0''M_0'' + E_1''M_1''$$

we find

$$(1 - n)f_0 = +0.5320 \times +91817 = +0.488466$$

$$nf_1 = +0.4680 \times +89747 = +0.420016$$

$$E_0''M_0'' = -0.0636 \times +1230 = -782$$

$$E_1''M_1'' = -0.0609 \times +1036 = -631$$

$$\text{Sum} = f_n = +0.90707$$

*Satellites of Saturn*

The adopted position of the ring-plane (page 832) is that of H. Struve. A revised position is given by G. Struve in *Veröffentlichungen der Universitäts-Sternwarte zu Berlin-Babelsberg*, Band VI, Heft 4, page 49; this position is being used in the *Nautical Almanac* from 1936 onwards. It has not been used in this *Almanac*, as the quantities  $U, B, P, U', B', P'$  on pages 622–623 were in print before the work on the preparation of the tables on pages 840–841 was begun.

# INDEX TO PLACES OF STARS, 1935

861

Mean places of stars between declinations  $+80^{\circ}$  and  $-80^{\circ}$  are given on pages 296-306 and of circumpolar stars on page 307. The page numbers given below are the pages on which the apparent places are to be found.

Name	Cat. No.	Page	Name	Cat. No.	Page	Name	Cat. No.	Page	Name	Cat. No.	Page
Phœnicis			Sagittarii			Sextantis			Ursæ Majoris

\* Now called  $\epsilon$  Libræ.

In the following index the subject should be sought under its principal noun, e.g. *Moon, phases of* and not *Phases of Moon*, or *Day, Julian* rather than *Julian Day*. The references given are usually to the tabular matter only, so that in many cases the information sought will be obtained by turning to the pages in the Explanation (pages 754-857) covering the tabular matter concerned.
